

The First "Computer Bug" Moth found trapped between points at Relay # 70, Panel F, of the Mark II Aiken Relay Calculator while it was being tested at Harvard University, 9 September 1945. The operators affixed the moth to the computer log, with the entry: "First actual case of bug being found". They put out the word that they had "debugged" the machine, thus introducing the term "debugging a computer program". In 1988, the log, with the moth still taped by the entry, was in the Naval Surface Warfare Center Computer Museum at Dahlgren, Virginia.

While <u>Grace Hopper</u> was working on the <u>Harvard Mark II</u> Computer at <u>Harvard University</u>, her associates discovered a <u>moth</u> stuck in a <u>relay</u> and thereby impeding operation, whereupon she remarked that they were "debugging" the system. Though the term <u>computer bug</u> cannot be definitively attributed to Admiral Hopper, she did bring the term into popularity. The remains of the moth can be found in the group's log book at the <u>Smithsonian Institution's</u> <u>National Museum of American History</u> in <u>Washington, D.C.</u>.^[1]

 A) Testování je demons 	trace, že v programu NEJSOU žádné vady?	
B) Testování demonstru	ije, že program provádí požadovanou funkcional	litu bezchybně?
C) Testování je proces,	který demonstruje, že program dělá to co má dě	ilat?
D) Testování je proces s	pouštění programu se záměrem nalézt vady?	
Testování vs. Zajištění ja	kosti (Quality Assurance)	
planning, preparatio	ng of all lifecycle activities, both static and dynar n and evaluation of a component or system and satisfy specified requirements, to demonstrate ct defects. (ISTQB)	related work products to
Activities focused or	providing confidence that quality requirements	s will be fulfilled. (ISTQB)

Důkaz, že v programu NEJSOU žádé vady:

Pokud je našim cílem ukázat, že v programu nejsou žádné vady, budeme podvědomě ovlivnění tímto cílem, což znamená, že budeme mít sklon použít data, u kterých je malá pravděpodobnost, že způsobí selhání. Na druhou stranu pokud našim cílem bude ukázat, že program má vady, budeme volit data, která mají větší pravděpodobnost objevení vady. Tento novější přístup je větším přínosem pro program než ten bývalý.

Testování ukazuje, že program provádí požadovanou funkcionalitu bezchybně:

Testování je proces, který demonstruje, že programdělá to co má dělat:

Program který dělá to co má pořád obsahuje vady. Což znamená, že pokud je v programu zřejmá vada program nedělá to co má, ale vady jsou v programu i když program dělá to co má.

Na testování programů je lépe nahlížet jako na destruktivní proces snažící se najít vady (jejichž přítomnost se předpokládá) v programu. Úspěšný testovací případ je ten, který posune vývoj tím způsobem, že způsobí selhání programu. Jistě, nakonec chceme použít testování k zajištění jistého stupně přesvědčení, že program dělá to co dělat má a nedělá to co dělat nemá, ale výše zmíněný přístup je nejlepší k dosažení nejlepšího výsledku v počtu nalezených vad.

• From testing user requirements to monitoring the system in operation:

Testing is not done only once (e.g. with the first version of the product), but it is an continuous activity throughout product's entire lifecycle (from user requirements, through system design and implementation, to monitoring the system in operation and its maintenance). Testing it most effective in early phases of the development.

From testing the functionality to checking all other aspects of software:

Testing is not focusing only to the system functionality but to all other attributes of the software:

- Documents (specifications)
- Design (model)
- Code
- Code+platform
- Production, acceptance
- Usage, business process

Verification:

Its goal is to answer the question: "Have we done the system correctly?" Verification uses a previous development step (i.e. functional specification prior to coding) as the reference. A piece of code that fulfils its specification is verified.

<u>Validation:</u>

Its goal is to check whether correct product has been built, i.e. whether it fulfils the customers needs. Thus, any step in the development process can be validated against user requirements.

The goal of testing may be verification or validation.

• <u>Testing can show the presence of errors but cannot show the absence of errors:</u>

There are still some errors never found in the software.

• <u>All defects can not be found:</u>

Even for simple programs/applications, the number of possible input combination or possible paths through the program is so large that all cannot be checked.

Testing does not create quality software or remove defects:

It is the responsibility of development.

<u>Building without faults means – among other – testing very early:</u>

Populární "argument" proti testování je: "Mněly by jsme tvořit bezchybně od samého začátku a ne hledat vady, když už je vše hotovo". Jistě. Ale "bezchybně od samého začátku" znamená mimo jiné, pořádně vše kontrolovat od samého začátku a po celý čas vývojového procesu. Inspekce specifikace požadavků a dokumentů návrhu může do jisté míry nahradit svstémové testv a akceptační testv. ale neznamená to "vývoj bez testování"!

• Perfect development process is impossible, except in theory:

In practice, the way from concept to ready product cannot be guaranteed to be error-free (inaccurate requirements specifications, cognitive errors, organizational errors). Therefore the need to test the final product, regardless how perfect development is.

Perfect requirements: cognitive impossibility:

Validation of requirements – are they what we really want? – is a kind of testing. But it is often impossible to define all requirements correctly in advance. Testing of the first version of a product is often a kind of additional requirements engineering: "is it what is really needed?

- <u>Poor communication:</u>
- If every test manager puts different meaning to each term, he/she spends lot of time on defining what is what.
- <u>Example: component module unit basic</u> <u>– design – developer, … testing</u>:
- Not only names differ but their precise meaning as well, which makes mapping difficult. Still worse if the same word means two completely different things, like "component" (either module, unit or "an independent component for component-based development").
- <u>There is no "good" and "bad" terminology,</u> <u>only undefined and defined:</u>
- Some people readily argue about the "right" names for things but almost any defined, standardized and generally accepted terminology is almost always better than a

- In *Development*, "money" (investment) result in *products*, that can be sold any yield revenue.
- In *Testing*, it's unclear from business perspective how "*money*" (investments) result in anything of value.
- *Testing* produces three kind of outputs:
 - risk information: probability that the product will fail in operation this information is necessary for better delivery decisions
 - *bug information*: input to development to enable them to remove those bugs (and, possibly, to the customer to let them avoid the bugs)
 - process information: statistics and other metrics allow to evaluate processes and organization and identify faults in them
- Unless there are *customers* for these outputs (managers willing to base their delivery decisions on test results, developers ready to fix defects found in testing, and process owners or projects managers ready to analyze and improve their processes), testing does not produce anything of value.
- In other words, high-level testing in low-level environment does not add any immediate value, except as an agent of organizational change.

- In *Development*, "money" (investment) result in *products*, that can be sold any yield revenue.
- In *Testing*, it's unclear from business perspective how "*money*" (investments) result in anything of value.
- *Testing* produces three kind of outputs:
 - risk information: probability that the product will fail in operation this information is necessary for better delivery decisions
 - *bug information*: input to development to enable them to remove those bugs (and, possibly, to the customer to let them avoid the bugs)
 - process information: statistics and other metrics allow to evaluate processes and organization and identify faults in them
- Unless there are *customers* for these outputs (managers willing to base their delivery decisions on test results, developers ready to fix defects found in testing, and process owners or projects managers ready to analyze and improve their processes), testing does not produce anything of value.
- In other words, high-level testing in low-level environment does not add any immediate value, except as an agent of organizational change.

The cost of discovering, localizing, correcting and removing a fault is often hundreds or thousands of times higher in ready product than it is in the early states of development. The cost of re-testing, regression testing, and updating or replacing the faulty software multiply very quickly after release (especially in mass production).

Test is most effective in early phases:

Contrary to traditional approach, test need not wait until development is ready. Test – reviews, inspections and other verification techniques for documentation and models - is actually the most effective in very early stages of any development process.

<u>Test measures and supports quality:</u>

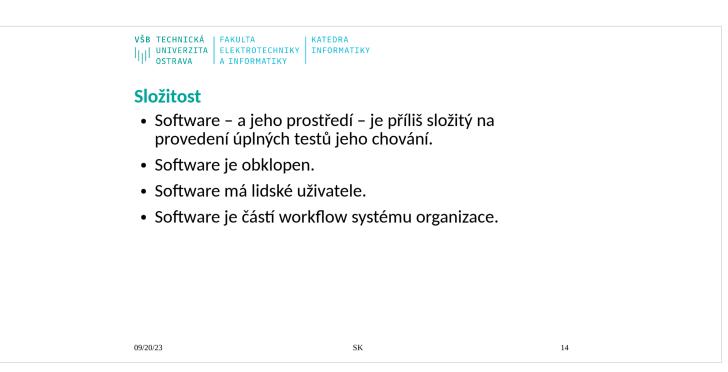

Test has two goals: to *measure* and *visualize* (the level of quality becomes known) quality and to support achieving quality by identifying product and process faults.

- <u>Testing is a part of Quality Assurance</u>:
- The goal is to achieve planned and known quality, not to test. If it could be achieved without testing, test would disappear. The goal for testing is therefore to minimize the volume of testing without compromising quality or to achieve as good (reliable) quality measurement as possible with given resources and time, not to "test as much as possible".
- Many qualities:
 - Functional quality: the system does what the user required.
 - *Non-functional quality*: these aspects (e.g. performance) are growing in importance. Cannot be reliably engineered without extensive testing.
 - *Quality attributes:* there are other attributes (e.g. maintainability, reusability, testability, ...) that must be check by testing too.
 - Usability for all stakeholders: "Usability" is not only important but multidimensional. What is comfortable for the operation may be uncomfortable for the end-user. Therefore growing need for measuring and quality assessment in this area.
 - Test techniques: tools and methods to measure quality efficiently and effectively:

Test theory contains knowledge how to test *efficiently* (so that desired levels of quality and test reliability are achieved) and effectively (so that it is done as cheaply as possible).

Test management: how to organize this:

Test management has much in common with general project and process management.

• Software is too complex to exhaustively test its behaviour:

Even for relatively simple programs/applications, the number of possible input combinations or possible paths through the program is so large that all cannot be checked. Then testing is necessary as a king of art of predicting under uncertainty, choosing the few tests we can afford to run that give us best confidence in program's future correct behavior.

Software environment is too complex to test it exhaustively:

A simple piece of code can be run on different PC-machines, OS (and their versions), with different printers, on different browsers. The number of combination easily becomes huge.

• Software can be embedded:

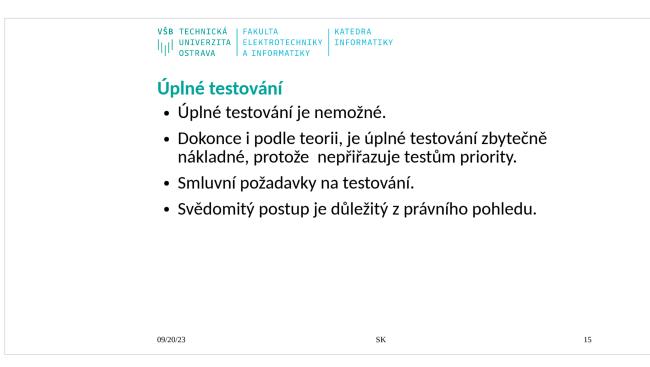

The testing products means testing SW, HW and "mechanics" around. Again, complexity. Again, methods required to make the best of this mess.

Software has often human users:

For most applications, the behavior (and needs) of the users cannot be fully predicted by the engineering means only. Testing (acceptance, usability) helps to tackle this aspect.

Software is part of the organization's workflow:

Engineering considerations are *not* the only important considerations for many software products. Any useful knowledge about product quality is a combination of engineering quality and the product's quality contribution during organizational or marketing usage.

- <u>Exhaustive testing is impossible:</u>
- Even for modest-sized applications with few inputs and outputs, the number of test cases quickly becomes huge.
- <u>Contractual requirements on testing</u>:
- The contract between the vendor and the customer may contain clauses on the required amount of testing, acceptable reliability levels, or even on specific test techniques or test coverage measures.
- <u>Non-negligent practice important from the</u> <u>legal point of view:</u>
- If you ever get sued by your customer, his or her lawyers will sure try the trick of accusing you of negligence because your testing was not "exhaustive". As defense, the impossibility of exhaustive testing should be

09/20/23	SK	16	

- <u>This is a risk-based, business decision:</u>
 - Test completion criteria must be specified in advance in test plan
 - Test prioritization criteria scales on which to compare test cases' relative importance (severity, urgency, probability, visibility, business criticality, etc.)
 - Decision strategy for the delivery must be specified in advance (what shall happen if test completion criteria are not fulfilled)
 - Test manager presents products quality he/she is responsible for the estimation and presentation of product quality but the business decision based on this data is made by responsible manager (project manager, project owner, product owner, etc.).
- <u>Test is never ready:</u>
- As exhaustive testing is not possible, we can always test a little more, and there is always some justification for it in (the diminishing) probability that more faults will be found. Unless completion criteria are established and test cases prioritized, the probability of finding more faults cannot be reliably estimated
- The answer is seldom "more testing" but rather "better testing":

Testing must be based on the combination of completion criteria:

- All test cases executed
- All test cases passed
- · No unresolved (serious) incident reports
- Pre-defined coverage achieved
- Required reliability (MTBF Mean time between

failures) achieved

Estimated number of remaining faults low enough

<u>Testing finds faults, which decreases the risk of failure in operation</u>
 Testing can be based on any criteria, but the most important is the risk of failure in operation as this is the most obvious indication of guality software.

- Risk-based testing
 - The chosen amount and quality of testing shall be based on how much risk is acceptable
 - Test design (choosing *what* to test) shall be based on the involved risks
 - The order of testing shall be chosen according to the risks
- <u>Error: the "mistake" (human, process or machine) that introduces a fault into software</u>:
 - <u>Human mistake</u>: users forget a need. Requirements engineer misinterprets users' need. Designer makes a logical mistake. Programmer makes a coding mistake.
 - <u>Process mistake</u>: requirements not uniquely identifiable, no routines for coping with changing/new requirements, not enough time to perform design inspections, poor control over programmers' activities, poor motivation, ...
 - <u>Machine mistake</u>: incorrect compiler results, lost files, measurement instruments not precise enough...
 - Fault: "bug" or "defect", a faulty piece of code or HW:

Wrong code or missing code, incorrect addressing logic in HW, insufficient bandwidth of a bus or a communication link.

• <u>Failure: when faulty code is executed, ti may lead to incorrect results (i.e. to failure):</u>

A faulty piece of code calculates an incorrect result, which is given to the user. A faulty SW or HW "crashes" the system. A faulty system introduces longer delays than allowed during heavy load.

When a failure occurs during tests, the fault may by identified and corrected. When a failure occurs in operation, it is a (small or large) catastrophe.

- <u>Testing finds faults, which decreases the risk of failure in operation</u>

09/20/23	SK	19

- <u>Famous: "Arianne", American Airlines booking system and more:</u> The financial cost can be shocking, many billions of dollars. As compared to the estimated cost of additional testing that would probably have discovered the fault (a few hundred thousand dollars).
 - Arianne: two faults that did not cause failures in the old rocket model. An overflow exception caused by a different start trajectory and missing exception handling code. Could easily be found if tested.
 - Americal Airlines: new booking system (1988) with complex mathematical algorithms for optimization of the numbers of business class and economy class passengers. It had a fault, which resulted in approximately 4 passengers fewer on every flight. Billions of lost revenue after a few months' operation were the first indication there was a fault at all!
- Quality of life:

As anyone using a PC or a buggy VCR software realizes, failures need not be catastrophes to sharply reduce the joy of living.

- Safety-critical systems:
- More and more safety-critical systems contain software the necessity of high safety and reliability grows. The cost of failure is injury or human life (railway, aircraft, medical systems). For many safety-critical systems the important attribute is usability (low usability can cause "operator mistake" or "human factor" in an accident, coming usually from confusing or unusable information, especially in stress situations).
- Embedded systems
- Embedded systems (whether safety-critical or not), require high-quality software, because of the difficulty (or impossibility) of updates. Remember the cost of software errors in some mobile phones.
- Usability requirements for embedded systems and Web applications:
- Embedded systems and Web applications are mass consumer products, where customers require easy usage. Failure to provide it results in lost revenues or market shares, which is a novel experience for software industry, used more to putting requirements on customers than the other way round!

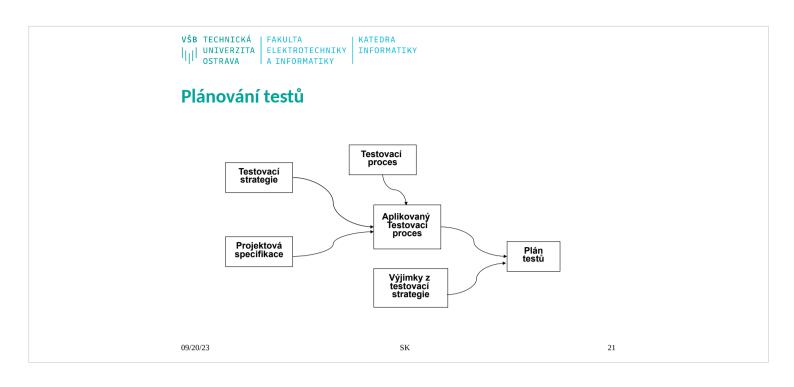

- <u>Test process as part of development or</u> production process
- Test is a part of QA, and test process should not be defined separately, but should be seen in the context of overall development process.

Large companies have own process definitions

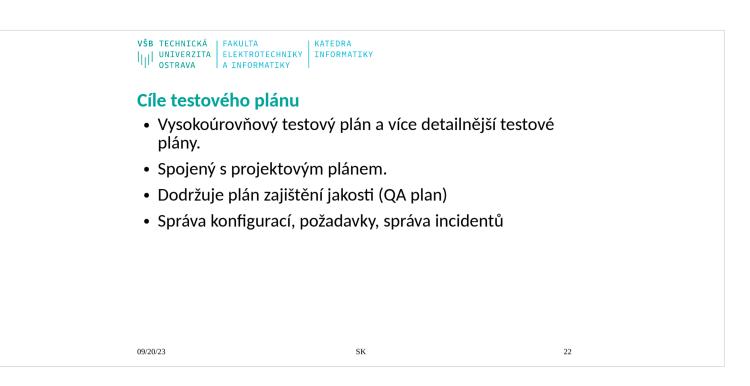

- Most development and production companies have own test processes. There can be of course similarities (though used terminologies are often strikingly different), but nevetheless many thousands different test processes exist in industrial reality.
- <u>"COTS" test process</u>

COTS (Commercial Off The Shelf)

It is possible to buy a test processes. The most known vendor today is probably IBM Rational with its RUP – Rational Unified Process (test

- A company's <u>Test Strategy</u> together with its <u>Test Process</u> (defined in the organization) are adopted to the current project based on a <u>Project Specification</u>. This results into an <u>Applied Test Process</u>, i.e. an overall vision "how we will test this time". This vision is the implemented (described in detail) in a <u>Test</u> <u>Plan</u>. Often, Test Plan is a document written in a natural language.
- The process of creating a Test Plan is test planning. The is mostly done very early during project. Later, the processes of test *estimation*, *monitoring* and *control* may lead to changes in the test plan.

Even the best test plan will not work unless it is synchronized with other areas, project and technical.

- <u>High-level test plan and more detailed test</u> <u>plans</u>
- Depending on project size and complexity, test plan can sensibly be divided into one highlevel test plan and some detailed test plans. The division can follow test area or test level, or specific aspects of testing.
- <u>Project plan</u>

Test plan must be inspected for correctness and compliance with overall project plan. Sometimes (in small projects) the test plan is the part of a project plan.

Follows the QA plan
 Hopefully, the function and contents of a test

Test specification defines what to test

Test specification are repositories of test cases. They should be free from organizational issues, which belong to the test plan(s).

<u>Test specification is part of testware</u>

Testware – test cases, test scripts, test data, etc. is often under CM control (manages either by test tool or by a separate tool).

• Basic building blocks of test specifications are test cases

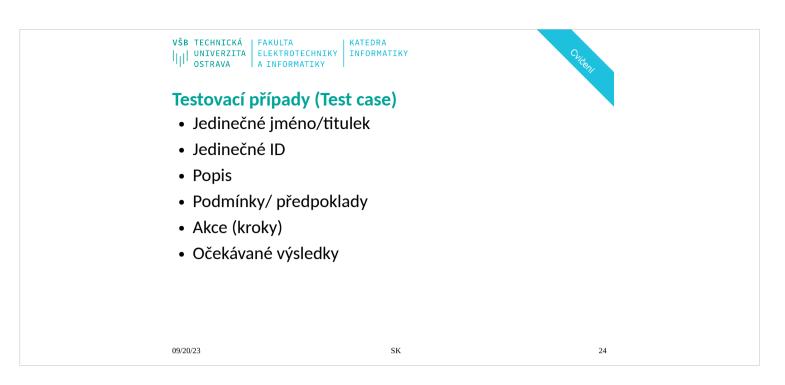

Test cases are generated when applying test design techniques. The shell be general and repeatable.

<u>Test specification – instruction – script</u>

Test cases need not contain all detailed information on *how* to perform them. This information may be put into a separate description, sometimes called *test instructions* (this approach is not practical because of maintenance difficulties).

If test execution is automated, then the instructions for a test tool are called *test script (test program)*. Test script can replace test case (instructions).

- <u>Test specification requirements</u>
- It is desirable that for every test case, there is a link to the requirements behind it and for every requirement, there are links to all test cases that verify it. This is very hard to achieve and maintain without using test tools (test management tools, e.g. Test Manager).
- <u>Test specification reporting</u>
- The test specification must support logging and reporting during and after test execution, mainly through the *identification* of test cases and their steps. This can be easily automated by using test tools (test running tools, e.g. Robot)

• <u>Unique name/title</u>

- Short test case title enhances readability of the specification and test reports descriptive unique name of the test case.
- Unique ID
- Identification of the test case. All test cases should follow an identical, defined format. This ID must be permanent (adding or removing test cases shell not change ID) – cryptic unique identification of the test case.
- Description

Brief description explaining what functionality the case case covers.

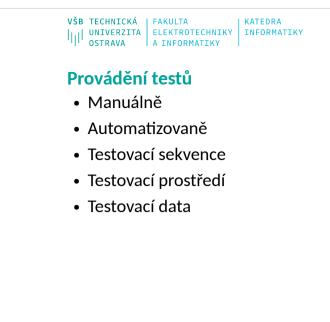

- <u>Preconditions / prerequisites</u>
 Exact description of required system state prior the execution of the test case.
- <u>Actions (steps)</u>

- Short test case title enhances readability of the specification and test reports descriptive unique name of the test case.
- Unique ID
- Identification of the test case. All test cases should follow an identical, defined format. This ID must be permanent (adding or removing test cases shell not change ID) – cryptic unique identification of the test case.
- Description

Brief description explaining what functionality the case case covers.

- <u>Preconditions / prerequisites</u>
 Exact description of required system state prior the execution of the test case.
- <u>Actions (steps)</u>

09/20/23

SK

26

Manual

Tester follows the description from the test case and performs step by step all specified actions. Prone to errors, boring (monkey testing) and time-consuming. It is recommended that the

- author of the test case performs it first.

• <u>Automated</u> Test tool executes test case according to predefined instructions (test scripts or test program). The automation scope can include any of / all of the following:

- Preparation (set-up to fulfill preconditions)
- Execution
- Result evaluation (comparing actual and expected results)
- Clean-up (putting system back into some known state)
- Test sequence

Sometimes it is not practical to execute each test case separately but it is better to put test cases into a sequence, e.g.:

- Insert new record
- Search existing record
- Modify existing record
- Deleté existing record

Test environment

There are more environments used for developing, testing and maintaining software applications (DEV – development, IT – functional and performance testing, QA – acceptance testing, PROD – production). Configuration files of test environment as part of testware are under CM control.

Test data

Test data are various input and output files (for expected and actual results) that must be managed properly as part of testware. If test data are taken from the production, they must be degradated.

 Záznam testů a Záznam aktuá výstupy. 	ních výstupů a porovnání s očekávaným
Off-line vyhod	nocování výsledků.
• Logování testů	I Contraction of the second
• Zpráva o teste	ch
• Záznam pokry	tí testy
• Zpráva incider	tů

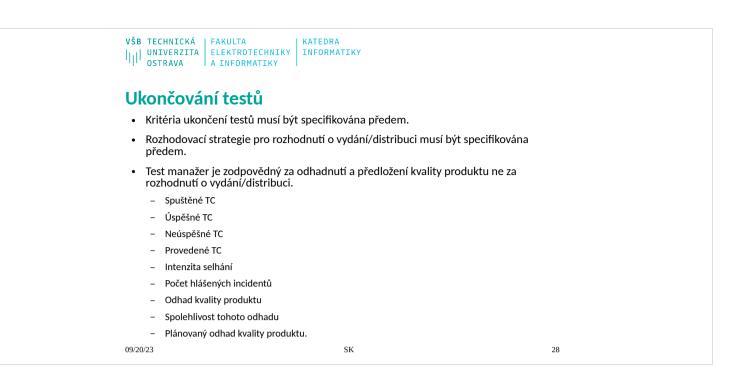

• <u>Recording actual outcomes and comparison against expected outcomes</u> <u>Manual testing</u>: If actual and expected outcomes match, then test case passed. If not, then test case failed, actual outcomes are recorded and incident (defect) is created and assigned to development. Automated testing: Comparison is done automatically, everything is recorded and even incidents are

- created.
- Off-line test result evaluation
- Sometimes the immediate result (pass/fail) is impossible (too fast execution to allow on-line evaluation by a lower analysis tool or the final result is available only after some other tests have been performed, etc.), so during test execution the results are gathered for the evaluation, which is done later.

Test log

It is a log of "all" (*relevant* and *important*) what happened during test execution. This activity (log creation) is best to automate, as it is repetitive, boring and requires exactness. It is used for (1) off-line evaluation,(2) failure analysis and debugging and (3) for archiving and future reference.

- Test report
- Is a summary of the results of all executed test cases. Must contain as well complete information on configuration and versions of test environment, testware and test object. Some test tools are capable to produce test report.
- Recording test coverage
- If test cases are mapped to requirements, test coverage can be easily derived. When executing test cases, the results are projected into requirements with the information how much functionality was successfully tested.
- <u>Incident management</u> Answer the following questions:
- Was this really a failure?
- 2. What presumably caused this failure?
- How to assign correction responsibility? 3.
- Incident must be repeatable put enough information to the incident report to enable reproducing the incident by the developer who is fixing it.

<u>Test completion criteria must be specified in advance</u>

In the test plan or similar document.

- Decision strategy for the release/delivery decision must be specified in advance
- What shall happen if test completion criteria are not fulfilled, but deadlines are approaching and there is strong pressure to release? The strategy for making this decision should be defined in advance.
- <u>Test manager is responsible for the estimation and presentation of the</u> product quality, not for release/delivery decision
- It is the responsibility of test manager to preset to project management accurate and up-to-date data on:
- 1. Number of percentage of run test cases
- 2. Number and percentage of passed tests
- 3. Number and percentage of failed tests
- 4. Trends in test execution (cumulative number of executed test cases)
- 5. Trends in failure intensity
- 6. Similar data on the number of incident reports, their status and trends
- 7. Estimation of product quality based on the data available
- 8. Reliability (level of significance) of this estimation
- 9. Projected estimation of product quality and test reliability for various scenarios

<u>All test cases executed</u>

It is a sensible criterion, provided good quality, coverage and reliability of those tests (otherwise the less test cases we have, the easier to achieve completion).

• <u>Àll test cases passed</u>

The previous criterion plus additionally that there must be no failed tests – strong requirement not achievable in practice.

- <u>No unresolved incident reports</u>
- It may be the same as the previous one but not necessarily: some incident reports may be postponed, rejected (e.g. caused by faults of test environment or testware, etc.).
- <u>No unresolved serious incident reports</u>

The previous criterion might be too strong – we can divide incident reports according to severity (e.g. 1 and 2 must be resolved).

Number of faults found

Generally a useless criterion, as it is the estimated number of *remaining* faults that matter. The assumption is that many found faults means few remaining (this can

- be wrong many found faults may mean many remaining).
- <u>Pre-defined coverage achieved</u>

Generally better that "all tests... no incidents..." family, because they address the issue of achieved test quality/reliability as well:

- <u>Code coverage</u>: there is a number of different code coverage measures that tell what proportion of tested code have been exercised by executed tests.
- <u>Functional coverage</u>: even very high code coverage does not guarantee that "all" (paths, user scenarios) has been tested. Therefore, it should be complemented by some kind of functional coverage.
- <u>Requirements coverage</u>: all code and all functions may have been tested, but in order to discover *missing* functionality, tests should cover all requirements.
- Required reliability (MTBF) achieved

This can only be calculated if statistical testing is used (MTBF – Mean Time Between Failures).

Estimated number of remaining faults low enough

Based on the number and frequency of faults discovered so far during testing, an estimation of the number of remaining faults can be made.

09/20/23	SK

• <u>Primary intent to find faults (NOT to prove correctness)</u> This comes from the definition of testing.

- <u>Testing is repetitive and detailed</u>
 Many activities which belong to testing are repetitive, requiring attention to detail. If not organized correctly, they may feel boring: not providing enough stimulation and variety.

30

- Testing brings bad news
- If the goal is to "succeed" and "deliver", then successful testing brings *bad* news (more work to development, delayed releases). Besides, when testers identify *failures*, developers feel sometimes accused of having made *errors* (which should not be the case, but often is).
- <u>Testing is "negative and destructive"</u>
 You sure recognize that terrible feeling when you have prepared a wonderful dinner, but your spouse (husband, wife)) fails to be impressed and notices instead a small stain on the tablecloth? Then you call him/her "negative and destructive". This is what testers do for a living...
- Testing career
- In some companies, the top level for a tester's advancement is Test Manager, whereas developers easily advance to Project Managers and into higher managerial levels. In reality, testers make better project managers and highlevel managers because they are used to see the whole instead of the details, to adopt the user perspective, to think in terms of risk estimation, to think in terms of quality. How to test then?
- - Attitude: successful test causes failures (finding faults, not hiding them, shall be rewarded).
 - Attitude and maturity ladder:
 - Testing equals debugging
 - Testing is to prove that it works Testing is to find where it does not work

 - Testing is to reduce the risk that it fails Testing is to measure and estimate the risk that it fails
 - Testing is mental attitude

 <u>Independent testing</u>
 Outsiders make better testers than insiders. However, debugging is better done by people with intimate knowledge of the way system is build.

- Test cases designed by the developer
- Test cases designed by someone else (developer)
- Test cases designed by another department
- Test cases designed by another organization (outsourced testing)

Test cases not designed by a person (generated automatically by tools)

Independence: not only test design, but planning, support, execution, evaluation

• <u>Metrics</u> By gathering and distributing metrics you help developers and management understand what test does.

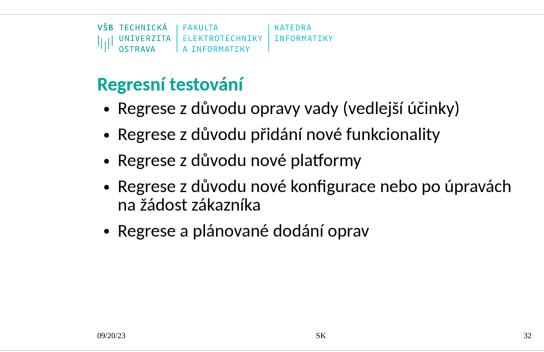

<u>Re-running of the test case that caused failure previously</u>

- A test case has caused a test object to fail. The fault that (supposedly) caused this failure has been discovered and removed (fixed). The very same test case is executed on the new (corrected) version of the system to ensure that the fault has really been successfully fixed.
- <u>Triggered by delivery and incident report status</u>
- Re-testing is normally done after the delivery of a fixed build and after the corresponding incident report has been put into a "fixed" ("corrected", "re-test", "put into build", or similar name) status. Some kind of private re-test before formal release may be used as well.
- Running of a new test case if the fault was previously exposed by chance

When failure occurred by chance without any intentional test case being executed (e.g. by "smoke-test", "sanity-check", or "ad-hoc" testing), a new test case should be designed and added. Re-testing means then the execution of this new test case.

- <u>Testing for similar or related faults</u>
- During re-testing, even test cases looking for *similar* faults may be executed. For example if a record deletion from a file caused failure, even other record deletion routines may be tested. Re-testing *related* faults is advisable too. For example if a record deletion method has been fixed, then other methods belonging to the same class can be re-tested after correcting the fault. This can be defined as "increased testing", or new test design caused by faults already found.

- <u>Regression due to fixing the fault (side effects)</u>
- On average, according to empirical data, 10-25% of all fixes actually introduce new faults, sometimes in areas seemingly "far away" (temporally, functionally or structurally) from the original fault. To be able to discover the new faults, test cases seemingly "far away" from the fixed fault must be executed on fixed builds.
- Regression due to added new functionality
- Adding new functionality may introduce faults into already existing functionality, or expose faults existing previously, but not found. Therefore, old functionality must be tested again for releases with new functionality.
- <u>Regression due to new platform</u>
- A system that executes correctly in one environment may fail in another environment, either due to hidden faults or interface faults. Therefore, regression testing may be required even when not a single software instruction has been changed.
- Regression due to new configuration or after the customization
- Sometimes called "configuration testing". For example, a Java script depends on HW, operating system and browser of the client machine. Including different versions of them, the number of possible combinations is very large, requiring impossibility large amount of regression testing. Special strategies are available to tackle this.
- <u>Regression and delivery planning</u>
- To decrease the amount of regression testing, a regression test suite may be run *once* on a release with *many* fault corrections and new functionality added. If an incremental methodology is used (e.g. RUP), then some increments (usually the latest ones) are focusing only on bug fixing which means that only re-testing and regression testing is needed. Regression testing is often used in *maintenance* when emergency fixes and "extra" functionality is introduced.

- <u>Less frequent deliveries</u> If a regression test takes longer than the time between releases, decreasing the delivery frequency may be an option. If a number of fixes and functionality enhancements are delivered together, less frequent deliveries are possible without increasing the overall development time.
- Round-robin scheme
- Example: A regression test suite has 300 test cases. It takes 1 day to execute 100 test cases. Releases come every day. Test cases no 1-100 are executed on release N, 101-200 on N+1, 201-300 on N+2, then again 1-100 on N+1, etc. Even if no release is fully regression tested, a relatively good measure of product quality is achieved.
 Additional selection of test cases
 The regression test suite may be pruned to fit the available time. A selection of regression test cases may be used for most releases, while the complete test suite will be executed only before external releases, quality checkpoints, instructure and the complete test suite will be executed only before external releases, quality checkpoints, and the complete test suite will be executed only before external releases.
- project milestones, etc.
- Statistical selection of test cases

Provided that the data on the probability distribution of user actions is available, test cases can be ordered according to their "importance", i.e. the relative frequency of the user action that they test. In this way, even if the complete regression test suite is not executed, the reliability level can be estimated for releases.

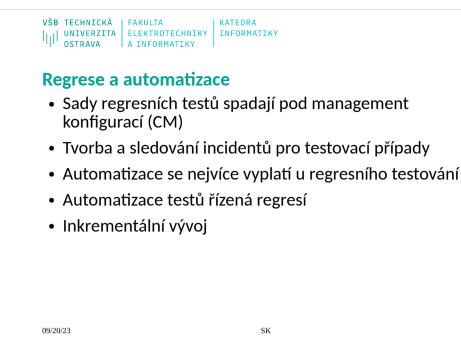

<u>Parallel testing</u>
 By dividing test execution into a number of parallel tracks, that can execute independently and in parallel, calendar test execution time can be significantly decreased. This applies both to manual and to automatic testing. The cost is that multiple amount of test equipment and of testers are required.

<u>"Smoke-test" for emergency fixes</u>
 Emergency fix – exceptional release that fixes one fault (or low number of faults) or sometimes introduces a new (small in scope) functionality and its delivery is urgently required. As changes in the system are relatively small,

- (small in scope) functionality and its delivery is urgently required. As changes in the system are relatively small, complete testing is not needed.
 "Smoke-test" or "sanity-check" means execution of a subset of the most important test cases from the regression suite with the goal to check if there is not major problem in the system after the change. Even in the emerging situation, some kind of "smoke-test" must be performed.
 Optimisation of regression suite

 General basic test techniques can help choose test cases for regression test suites effectively. Required level of test coverage can be used to estimate the needed amount of regression testing. Good system understanding is required to identify and remove repetitive or less important test cases.

 Redundant test cases can be removed.
 - History regression test cases may become obsolete with time. Stable functionality where faults are no longer discovered during regression testing, need not be tested as extensively as new, unstable
 - functionality, or as a system area with a history of many faults. *Dependencies* provided a well-designed system with clear-cut dependencies and interfaces, it is possible to minimize the amount of regression for areas that are not related and not connected to the area, where recent changes have occurred. Test-level co-ordination – savings in regression test time can often be achieved by coordinating tests
 - run on different levels, to avoid reperition.

34

Regression test suites under CM control

- All test cases shell be archived and under version control to be able to return back to already not used test cases. Regression test cases are changing from release to release. This applies even more to automated regression testing which increases the amount of testware: test scripts, test programs, test data, test configurations, etc.
- Incident tracking for test cases
- Test cases (especially test scripts, test programs, test data) can be faulty or changed for other reasons (e.g. effectiveness). These changes should be controlled and traceable like any software changes. The development and maintenance of testware should be handled like development and maintenance of any other software, i.e. planned, designed, under version management. etc.

Automation pays best in regression

When test automation is considered, it shall be first of all applied to regression testing. The strategy for regression testing must therefore be known before the automation strategy is developed. Large amount of regression requires automation (the automation is effective starting from number of releases > 3). Performance testing cannot be done without tools (load generation, monitoring, performance measurement, etc.). These tools and test cases may therefore be candidates to be included in regression testing.

Regression-drive test automation

Introducing test automation into projects must be planned according to the needs of the regression test strategy. Incremental development

- New development methods ("incremental development", "daily build", "Rapid Application Development", RUP, etc.) become increasingly popular. They are characterized by frequent deliveries, incremental functionality growth, and fast feedback from test to development. Therefore, they require heavy regression testing, which makes both test automation and other techniques for regression optimization especially important.

		KATEDRA INFORMATIKY

	 Výsledky jsou částí tes (CM) 	stware – Management konfigi	urací
0!	/20/23	SK	35

<u>Test = measuring quality = comparing actual outcome with expected outcome</u>
 Test is verifying whether something is correct or not – means by definition comparing two values: actual and expected. Random testing is (1) normally not really testing at all (2) or testing actual results against our vague and unspecified outcome expectations.

What about performance measurement?

Performance measurement = benchmarking.

Performance requirements are notoriously vague or absent, but performance testing is thriving. Explanation? It is then either testing against informal, unspecified "random requirements" or a kind of requirement engineering (trying to find out what the requirements should be) by running ready product.

Results = outcomes; outcomes ≠ outputs

Application outputs can be test case outcomes, but not all test cases outcomes are outputs – performance levels, state transitions, data modifications are possible test case outcomes which are not application outputs. In order to evaluate them, test environment must provide access to them: through special test outputs, debug tools, etc.

Test case definition: preconditions – inputs – expected outcomes

- When expected test result/outcome is missing, then it is NOT a test case specification at all. Unspecified or insufficiently specified expected outcomes make some failures harder to discover.
- <u>Results are part of testware CM control</u>
- Often, the expected outcome is a data file. Unless it can be incorporated in a test specification, it will require to be under separate CM control. Changing the expected outcome file will have the same effect as directly changing the test specification a common baseline for them will therefore be required.

36

Outputs

They are most easily observable, therefore often utilized as outcomes/results. Outputs have very many forms: displayed or changed GUI objects, sent messages or signals, printouts,

SK

sounds, movements.

09/20/23

State transitions

Does the system perform correct state transition for a given set of inputs? Outputs following transitions are often used to judge, but the new state is the expected outcome.

• <u>Data changes</u> Has data changed correctly?

<u>Simple and compound results</u>
 Results may be simple ("Error message appears") or compound ("new record put into database, index updated, display adjusted, message sent...").

"Long-time" results

For example, testing for long-time stability: system still works correctly after a week. Quality attributes (time, size, etc.)

Most non-functional requirements are of this kind. • <u>Non-testable?</u>

- Possibly valid requirements, but formulated in a non-testable way, e.g. "sufficient (1)throughput to handle typical traffic".
- (2) Valid, measurable requirements, which cannot be measured due to technical constraints. Side-effects
- Implicitly, every test case has an invisible clause in expected outcome definition "the program does this... and nothing incorrect happens". "Nothing incorrect" is easily implied, but impossible to verify.

VŠB TECHNICKÁ FAKULTA KATEDRA UNIVERZITA ELEKTROTECHNIKY INFORMATIKY OSTRAVA A INFORMATIKY
Zdroje výsledků
Nalezení nebo spočítání správných očekávaných výsledků je mnohdy mnohem těžší než by se mohlo zdát. Je to hlavní úloha při přípravě testovacích případů.
• Požadavky
• Oracle
• Specifikace
Existující systém
 Jiné obdobné systémy
• Standardy
• NE kód
09/20/23 SK

- Requirements
- Sufficiently detailed requirement specifications can be used directly as the source of expected test résults. Most often however, requirements do not have sufficient quality.

37

- Oracle
- According to BS 7925-1 it is "a mechanism to produce the predicted outcomes to compare with the actual outcomes of the software under test"; often a program, another similar application, etc.
- Specifications

Specifications other than requirement specification (e.g. design specification, use case specification, interface specification, function specification) are generally a good source of expected outcomes – verification means testing whether system works "according to specification".

• <u>Existing systems</u> Previous, verified versions of the same system can be used as oracle for getting correct expected results.

Other similar systems

Any other software – commercial or not – that has already been sufficiently verified and

- implements part of the functionality of the tested system, often makes a good oracle. <u>Standards</u>
- Many standards, e.g. in telecommunications, contain detailed specifications that can be used as expected test results. A good example of a test case suite built entirely around standard specification is Sun's test suite for verification whether a JVM (Java Virtual Machine) conforms to Sun's Java standard.
- NOT code

(nor the same specification if specification is the test object), Because anything compared to itself (the same source of expected and actual outcomes) will always give "correct" results.

VŠB TECHNICKÁ FAKULTA UNIVERZITA ELEKTROTECHNIKY OSTRAVA A INFORMATIKY	KATEDRA INFORMATIKY	
Obtížnost porovnání		
• GUI		
 Komplexní výsledky 		
Absence vedlejších et	fektů	
 Časový aspekt 		
 Neobvyklé výstupy (n 	nultimedia)

 Komplexní výpočty 		
 Inteligentní a "fuzzy" 	porovnání	
09/20/23	SK	38

<u>GUI</u>

- Notoriously difficult expected results. Prone to frequent changes, complex, often asynchronous. If treated on pixel level, often useless, require some kind of object approach. Most tools existing today do not cope well with moving or scrolling components.
- <u>Complex outcomes</u>
 Actually, GUI outputs are one of them. Comparison may be difficult simple because the results are large and complex.
- <u>Absence of side-effects</u> For most test cases, there are infinitely many possible outcomes that must not happen. For a test case "press key" with expected outcome "text <<key pressed>> appears" there are innumerable things that are expected NOT to happen: program does not crash, database is not deleted, no - say - blinking green triangle appears in the middle of the screen... etc. Verifying this is impossible, on the other hand some degree of observant caution is necessary.

• <u>Timing aspects</u> Outcomes that either occur very quickly or last very short time, or are asynchronous, or occur after undefined delay may all be hard to verify correctly.

Unusual outputs (multimedia)

Video sequences, complex graphics, sounds, smells, etc. are very hard to test.

- Real-time and long-time difficulties
 (it is a sub-set of "absence of side effects")
 For real-time, multithread applications there may exist hidden faults that only cause failure when certain
 rare timing conditions are fulfilled. Such failures are not easily repeatable. During long-time
 execution a gradual "decay" of software may occur (stability testing aims at those problems). Typical
 example of such problems are memory-leaks.
- Complex calculations

Their results are hard to verify, may only "look right". AA booking system fault 1988.

<u>Intelligent and "fuzzy" comparisons</u>
 Whenever correct result is not fully deterministic or analogue rather than discrete, it is difficult to verify.

VŠB TECHNICKÁ FAKULTA UNIVERZITA ELEKTROTECHNIKY OSTRAVA A INFORMATIKY		
1.7-Prioritizace testů		
Proč prioritizovat testovací p	řípady?	
 Určit důležitost a pořadí (v 	čase)	
 "Nikdy není dost času"

 Je těžké udělat dobrou prie s různou váhou). 	oritizaci (vícenásobná kritéri	a
09/20/23	SK	39

- <u>Decide importance and order (in time)</u>
 To prioritize test cases means to measure their importance on an ordinal scale, then plan test execution accordingly (typically, in descending order of importance, i.e. more important cases before less important).
- <u>"There is never enough time"</u>
 Dedicated testers easily become paranoid they suspect faults everywhere and want to verify every tiny detail. To balance this desire with business reality, we must choose what is most important to test, i.e. prioritize.
- <u>Testing comes last and suffers for all other</u> <u>delays</u>
- The day for customer delivery is often holy, but development is nevertheless delayed. Planned test time is cut as a result, often with

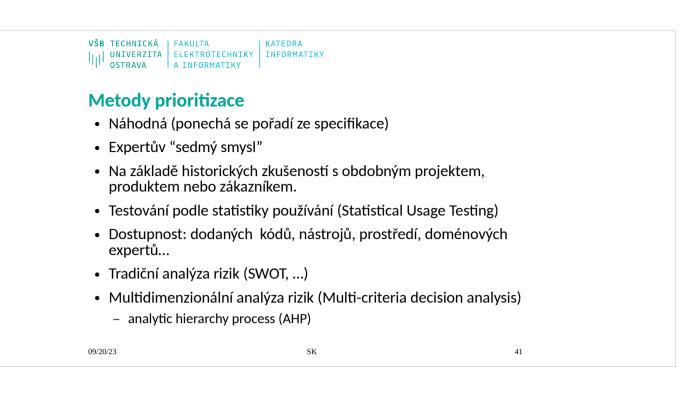

Prioritní kritéria	
 Vážnost (selhání) 	 Co zákazníci chtějí
 Priorita (urgentnost) 	 Náchylnost ke změně
 Pravděpodobnost 	 Náchylnost k selhání
Viditelnost	 Kritické z hlediska byznysu
 Priorita požadavků 	 Složitost (testovaného
 Zpětná vazba na/od 	objektu)
vývojářů	 Obtížnost opravy

This is a tentative list of possible prioritization criteria (scales on which to compare test cases' relative importance). This list is not ordered (i.e. it gives no clue to which criteria are more important). The critéria are not independent nor exclusive. For operational usage, they must be defined more in details. Put them into columns are mark each test case with the level of importance:

- H high M medium
- L low
- Severity (failure); the consequences of failure (in operation): 1 fatal, 2 serious, 3 –
- <u>Severity (lattre)</u>, the consequences of lattre (in operation). 1 latal, 2 senous, 3 disturbing, 4 tolerable, 5 minor
 <u>Priority (urgency)</u>: how important it is to test this particular function as soon as possible: 1 immediately, 2 high priority, 3 normal queue, 4 low priority
 <u>Probability</u>: the (estimated) probability of the existence of faults and failure in operation
 <u>Visibility</u>: if a failure occurs, how visible it is? (it relates to "severity")

- Requirement priorities: if requirements are prioritized, the same order shall apply to test cases
- Feedback to/from development: do the developers need test results to proceed? (similar to "priority"). Do the developers know a specific tricky area or function?
- Difficulty (test): is this test case difficult to do (resource- and time-consuming?)
- What the customer wants: ask the customer what he prefers (it relates to "requirements priorities")
- Change pronéness: does this function change often?
- <u>Error proneness:</u> is it a new, badly designed, or well-knows "stinker" feature? <u>Business criticality:</u> related to "severity" and "what the customer wants" <u>Complexity (test object)</u>: related to "error proneness"

- Difficult to correct: a fault known to be difficult to correct, may be given lower priority (provided severity is sufficiently low)

- <u>Random (the order specs happen)</u>
 No method at all, but "the order test specs happen" may actually mirror both the "priority" and "business criticality" as well as "requirements prioritization" – the not so bad.
- Experts' "gut feeling"
- Experts with testing, technical and domain (application) knowledge do the prioritization. Experts are good to have, but their "gut feeling" may often be misleading, unless structured methods (see below) are followed.
- <u>Based on history with similar projects</u>, products or customers
- Documented data on previous fault history, priority, severity, etc. is used to prioritize test cases for current project/product according to some chosen criterion (or a chosen

Testing is not only test execution. Static analysis can be performed before the code has been written. Writing and designing test cases is also part of testing. Reviews of requirement specifications and models, and of any other documents, belong to testing as well.

VŠB TECHNICKÁ FAKULTA KATEDRA UNIVERZITA ELEKTROTECHNIKY INFORMATIKY OSTRAVA A INFORMATIKY
IEEE standards
3.1.36 verification:
 (A) The process of evaluating a system or component to determine whether the products of a given development phase satisfy the conditions imposed at the start of that phase.
 (B) The process of providing objective evidence that the software and its associated products conform to requirements (e.g., for correctness, completeness, consistency, accuracy) for all life cycle activities during each life cycle process (acquisition, supply, development, operation, and maintenance); satisfy standards, practices, and conventions during life cycle processes; and successfully complete each life cycle activity and satisfy all the criteria for initiating succeeding life cycle activities (e.g., building the software correctly).
3.1.35 Validation:
 (A) The process of evaluating a system or component during or at the end of the development process to determine whether it satisfies specified requirements.
 (B) The process of providing evidence that the software and its associated products satisfy system requirements allocated to software at the end of each life cycle activity, solve the right problem (e.g., correctly model physical laws, implement business rules, use the proper system assumptions), and satisfy intended use and user needs.
• NOTE—For (A), see IEEE Std 610.12-1990 [B3].
 NOTE—For subdefinition (A) see IEEE Std 610 12-1990 [B3]

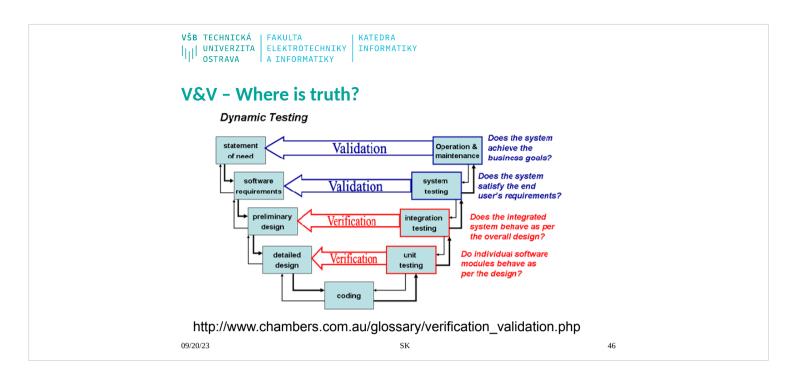

• NOTE—For subdefinition (A), see IEEE Std 610.12-1990 [B3].

Requirements Analysis

During the requirements analysis phase, basic market research is performed and potential customer requirements are identified, evaluated, and refined. The result of this phase of the process is usually a marketing requirement or product concept specification. Requirements in the concept specification are usually stated in the customer's language.

Requirements Definition

Requirements in the concept specification are reviewed and analysed by software engineers in order to more fully develop and refine the requirements contained in the concept specification. Requirements from the concept specification must be restated in the software developer's language - the software requirements specification.

D<u>esign</u>

Once the SRS is developed, software engineers should have a complete description of the requirements the software must implement. This enables software engineers to begin the design phase. It is during this phase that the overall software architecture is defined and the high-level and detailed design work is performed. This work is documented in the software design description.

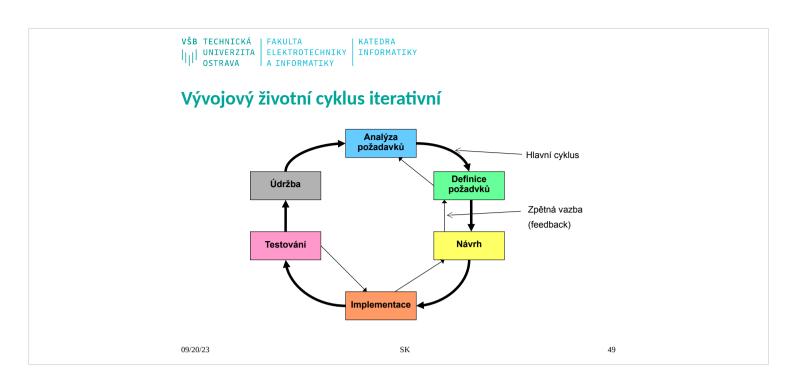

<u>Coding</u> The information contained in the SDD should be sufficient to begin to the coding phase. During this phase, the design is transformed or implemented in code. If the SDD is complete, the coding phase proceeds smoothly, since all of the information needed by software engineers is contained in the SDD.

Testing

According to the waterfall model, the testing phase begins when the coding phase is completed. Tests are developed based on information contained in the SRS and the SDD already in the coding phase. These tests determine if the software meets defined requirements. A software validation test plan defines the overall validation testing process. Individual test procedures (test cases, test scripts, test programs) are developed based on a logical breakdown of requirements. The results of the testing activities are usually documented in a software validation test report. Following the successful completion of software validation testing, the product may be shipped to customers.

Maintenance

Once the product is being shipped, the maintenance phase begins. This phase lasts until the support for the product is discontinued. Many of the same activities performed during the development phases are also performed during the maintenance phase.

Requirements Analysis

During the requirements analysis phase, basic market research is performed and potential customer requirements are identified, evaluated, and refined. The result of this phase of the process is usually a marketing requirement or product concept specification. Requirements in the concept specification are usually stated in the customer's language.

Maintenance

Once the product is being shipped, the maintenance phase begins. This phase lasts until the support for the product is discontinued. Many of the same activities performed during the development phases are also performed during the maintenance phase.

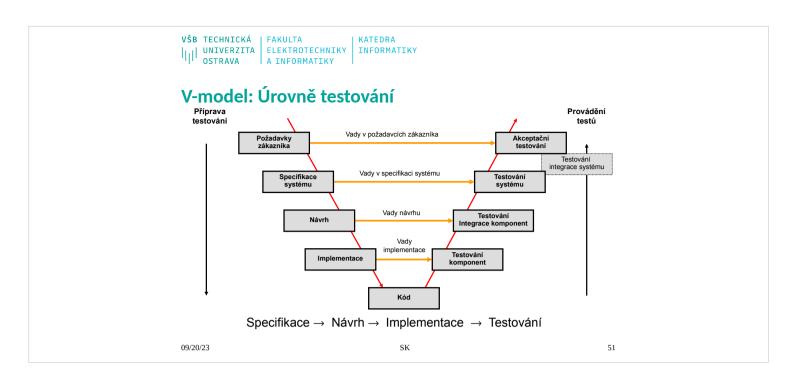

• <u>Waterfall</u>

There is no ideal model. Waterfall model is the right one in ideal world. Analysis - 1 understand everything Design - I design perfect solution with complete and right knowledge of customer and target platform Coding - Design is coded without bugs Testing - Well, why the hell test ideal system? Testing can be omitted... Eureka!!! the system is accepted and it fulfills all stakeholder needs but ideal does not exist in reality therefore waterfall model is out of touch with reality

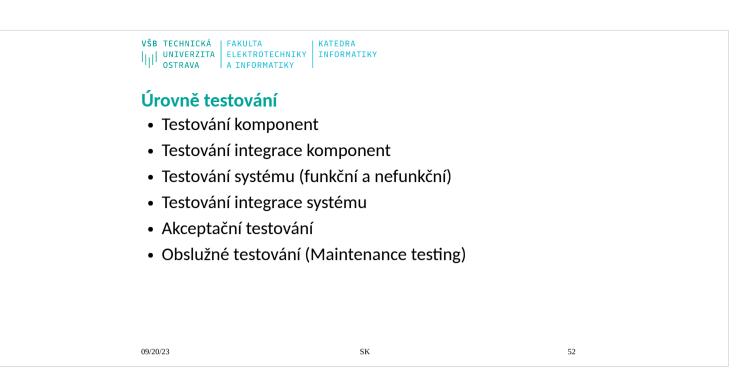

• <u>Iterative (RUP, SCRUM)</u> The development is divided into iterations. In the

first iteration we focus on a big picture. The project is split into small pieces (iterations), in which we deliver product to the customer to get customer feedback. Iterations are here to reduce time we are walking the wrong way (one iteration usually takes 2- 3 weeks). The iteration must not be changed during processing, all plans/bugs/etc must be planned for the next iteration. There must be no disturbance from the iteration plan focus on the target. The iteration should end as planned and evaluated. Unfinished tasks together with bugs found in this iteration must be estimated again and planned for the beginning of the next iteration. Do not save bugs for later, unfixed bug means the work was not done. One or two iterations are planned just to remove bugs (no new functionality is implemented). In SCRUM terminology an iteration is called a Sprint.

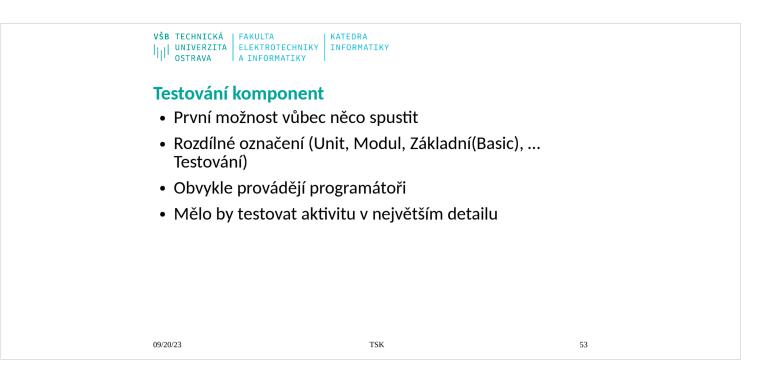

- <u>Extreme programming (XP)</u>
- It goes about agile software development methodology (rapid development), the set of daily practices that embody and encourage particular XP values: communication (simple design, common metaphors, collaboration of users and programmers, frequent verbal communication and feedback), simplicity (starting with the simplest solution), feedback (from the system by writing unit tests and running periodic integration tests, from the customer by acceptance testing, from the team by quick response to new requirements), courage (design and code for today and not for tomorrow - developers feel comfortable with refactoring their code when necessary) and respect between team members.

- For each stage in the model there are deliverables to the next stage, both development and testing. Such a delivery is an example of a baseline.
- For example, when the user requirements are ready, they are delivered both to the next development stage and to the corresponding test level, i.e. acceptance testing. The user requirements will be used as input to the system specification (where the system requirements will be the deliverable to the next stage) and the acceptance test design. Note that this is a simplified model. In reality, the arrows should point in both directions since each stage naturally will find faults and give feedback to the previous stages.

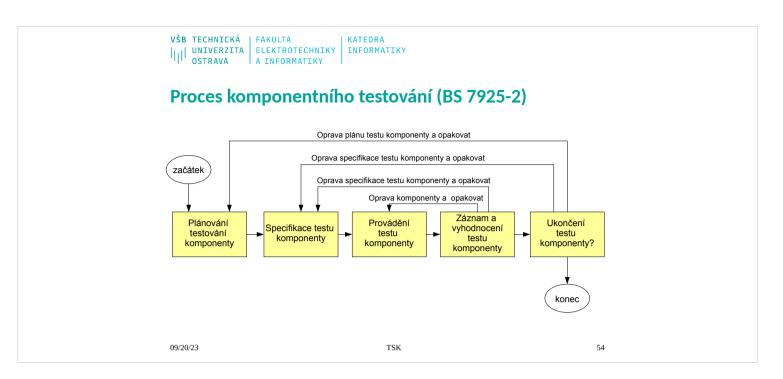

- The objectives are different for each test level (see the V-model)
- Test techniques used (black- or white- box)
- Object under test, e.g. component, grouped components, sub-system or complete system
- Responsibility for the test level, e.g. developer, development team, an independent test team or users
- The scope of testing

The objective of component (unit, module) testing is to find bugs in individual components (units, modules) by testing them in an isolated environments. Component testing is the first *dynamic* testing activity in the development life cycle. Traditionally (and most practically) component testing have been performed by programmers. One major reason for this is that component testing tends to require knowledge of the code which is why developers are well suited for this. Unfortunately component testing is often viewed more as a debugging activity than as a testing activity.

<u>Mature ladder:</u>

• Developers are checking their own modules with little or no documentation (they are blind

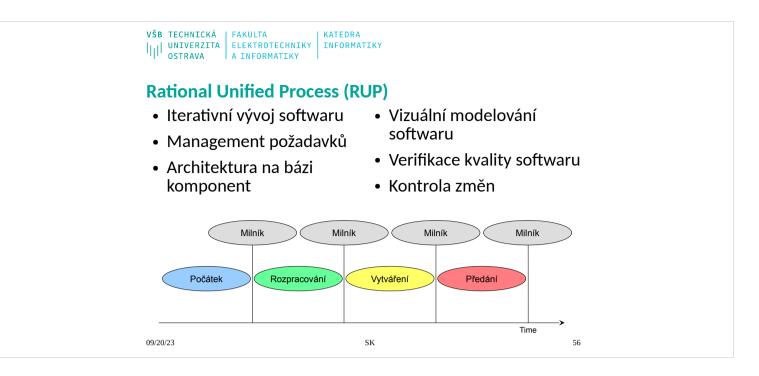

- <u>Component Test Planning</u>
 The component test planning contains two phases. *In the first phase* the overall project test strategy (generic) and the project test plan (project specific) are defined. The project test strategy includes test case selection methods, the project test phase itself. The project test phase itself are contained to the component test process itself. documentation, entry and exit críteria as well as the component test process itself. The project test plan contains information of the scope of the project, the resources needed and how to apply the strategy in the current project. <u>The second phase of the planning deals with components individually. For each component a separate</u> component test plan is produced (to list the specific test case design techniques, the test measurement techniques, the tools including stubs and drivers and the test completion criteria that apply to the specific component)
- Component Test Specification Component test specification is the activity of applying the test design techniques specified in the component test plan to the information in the design specification, producing a number of test cases. The test cases should be documented in the component test case specifications. Each test case should also have a unique name and contain enough detailed instructions on how to perform the test case and a reference to the requirement that is tested by that test case.
- Component Test Execution
- During component test execution, the test cases are executed on the actual module, preferable in the priority order. However, things might happen during the execution of the test cases which may force deviations from the planned order of execution. This is normal and quite all right as long as the deviations are conscious choices. Component Test Recording
- During the execution of test cases, test results are produced. Basically there are two types of results: logs and pass/fail results. A log is just a chronological list of events that took place during the execution. The second type of result is the result of comparing the actual and the expected output. After a fault is located it usually pays off to investigate where the fault was first introduced in the design process and it is a good practice to correct the fault in all documents that contain the fault. A component test report is the document which contains a summary of all results of the second type.
- Component Test Completion? Based on the information in the component test reports, the specified exit criteria in the test strategy and/or the test plans, and the current time budget, the decision whether or not to continue testing, can be performed. Here there are also several options:
 - Enough coverage has been obtained and quality of test object is OK => component testing can be ended and the component delivered to the next level of testing (usually to component integration testina)
 - All test cases have been executed but enough coverage has not yet been achieved => more test cases have to be designed and executed to increase the coverage.
 - Time is out but the quality of the test object is too low => negotiate with project stakeholders to get more time to test and to correct faults (this is however typically NOT the responsibility of the test subproject).

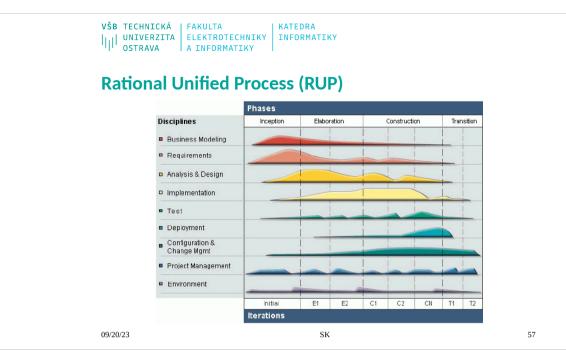

- Algorithms and logic:
 - Have algorithms and logic been correctly implemented?
- Data structures (global and local):
 - Are global data structures used?
 - If so, what assumptions are made regarding global data?
 - - Are these assumptions valid?
 - Is local data used?
 - Is the integrity of local data maintained during all steps of an

algorithm's execution?

RUP is an example of object-oriented methodologies that emphasize the incremental, iterative, and concurrent nature of software development.

- RUP is a product process developed by Rational Software Corporation that provides project teams with a guide to more effective use of the industry-standard Unified Modeling Language (UML). RUP also provides softwareengineering best practices through templates, guidelines, and tools. Most of the tools are, as you might guess, also provided by Rational.
- The RUP is based on four consecutive phases. The purpose of the *inception phase* is to establish the business case for the project. This is done by creating several high-level use case diagrams, defining success criteria, risk assessment, resource estimate, and an overall plan showing the four phases and their approximate time frames. Some deliverables the inception phase might include are:
- A vision statement
- An initial set of use cases
- An initial business case
- An initial risk assessment
- An initial project plan
- Prototypes
- The purpose of the <u>elaboration phase</u> is to analyze the problem domain, establish the overall product architecture, eliminate the highest risks, and refine the project plan. Evolutionary prototypes are developed to mitigate risks and address technical issues and business concerns. Some key deliverables this phase might include are:
- A relatively complete use case model supplemented with text as appropriate
- Architecture description
- Revised risk assessment
- Revised project plan
- Initial development plan
- Initial user manual
- During the <u>construction phase</u>, the remaining components are developed, and thoroughly tested. Key deliverables from this phase include:
 Software product operating on target platform
- Revised user manual
- Complete description of current release
- The purpose of the transition phase is to transition the product from development to the user community. Activities that would typically be performed include:
- Beta testing by users
- Conversion of existing information to new environment
- Training of users
- Product rollout

1. Add a test

2. Run all tests and see if the new test fails

This validates that the test harness is working correctly, shows that the new test does not pass without requiring new code because the required behavior already exists, and it rules out the possibility that the new test is flawed and will always pass. The new test should fail for the expected reason. This step increases the developer's confidence in the new test.

3. Write the code

The next step is to write some code that causes the test to pass. The new code written at this stage is not perfect and may, for example, pass the test in an inelegant way. That is acceptable because it will be improved and honed in Step 5.

At this point, the only purpose of the written code is to pass the test. The programmer must not write code that is beyond the functionality that the test checks.

4. Run tests

If all test cases now pass, the programmer can be confident that the new code meets the test requirements, and does not break or degrade any existing features. If they do not, the new code must be adjusted until they do.

Ir	dividual best practices states that one should
•	Separate common set-up and teardown logic into test support services utilized by the appropriate test cases.
•	Keep each test oracle focused on only the results necessary to validate its test.
•	Design time-related tests to allow tolerance for execution in non-real time operating systems. The common practice of allowing a 5-10 percent margin for late execution reduces the potential number of false negatives in test execution.
•	Treat your test code with the same respect as your production code. It also must work correctly for both positive and negative cases, last a long time, and be readable and maintainable.
•	Get together with your team and review your tests and test practices to share effective techniques and catch bad habits. It may be helpful to review this section during your discussion.

Te	st Driven Development
Му	th
Reali	TDD doesn't scale
This is	s partly true, although easy to overcome. TDD scalability issues include:
1)	Your test suite takes too long to run. This is a common problem:
	 First, separate your test suite into two or more components. One test suite contains the tests for the new functionality that you're currently working on, the other test suite contains all tests. You run the first test suite regularly, migrating older tests for mature portions of your production code to the overall test suite as appropriate. The overall test suite is run in the background, often on a separate machine(s), and/or at night.
	 Several levels of test suite development sandbox tests which run in 5 minutes or less, project integration tests which run in a few hours or less, a test suite that runs in many hours or even several days that is run less often.
2)	Not all developers know how to test.
	That's often true, so get them some appropriate training and get them pairing with people with unit testing skills.
3)	Everyone might not be taking a TDD approach.
	 Taking a TDD approach to development is something that everyone on the team needs to agree to do.
	they either need to start they need to be motivated to leave the team
	they need to be mouvaled to leave the team team should give up on TDD.

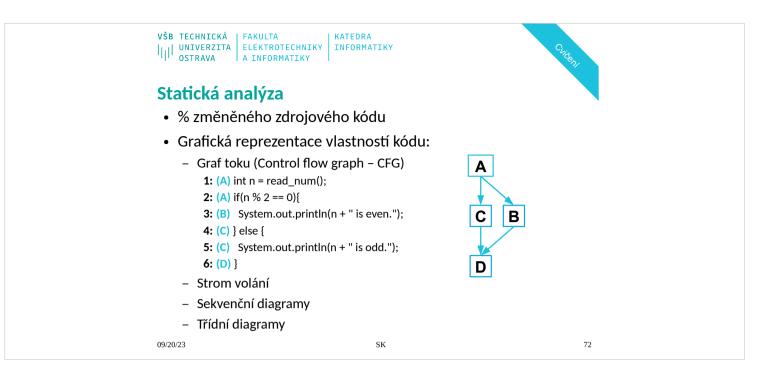

09/20/23

SK

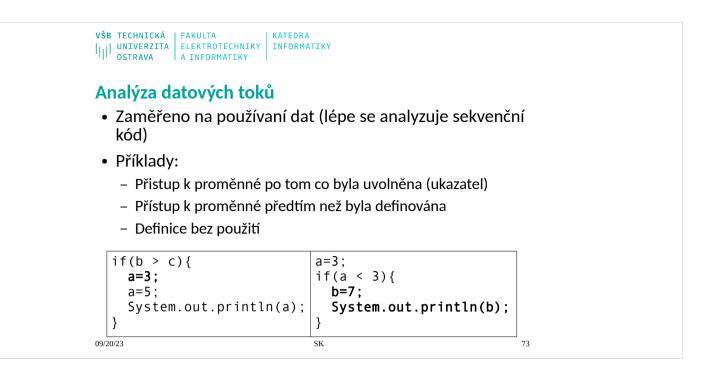

• <u>Unreachable code</u>

- Part of a code that you can't reach, e.g. uncalled functions or procedures. Also called *dead code*.
- Parameter type mismatches
- E.g. a variable declared with one type is sent to a procedure, but the procedure expects a variable of another type.
- <u>Possible array bound violations</u>
- Trying to access an element index outside the boundary value of the array.
- Faults found by compilers
- Fault types found by compilers depend first of all on the language – what is legal in it. For example, data type mismatches, missing files, possible division by 0, ranges without stop value, misuse of variables.

• <u>% of the source code changed</u>

- Some tools can analyse and tell how many % of the source code have been changed and which parts that have been changed => input to test case generation.
- *Graphical representation of code properties* Depends on development tools features.

Note: Not to be confused with *data flow testing* which is a dynamic test case selection method.

• <u>Considers the use of data</u>

How are the variables used through the code?

• Definitions with no intervening use IFB > CTHEN A = 3;

A = 3; IF A < 3 THEN

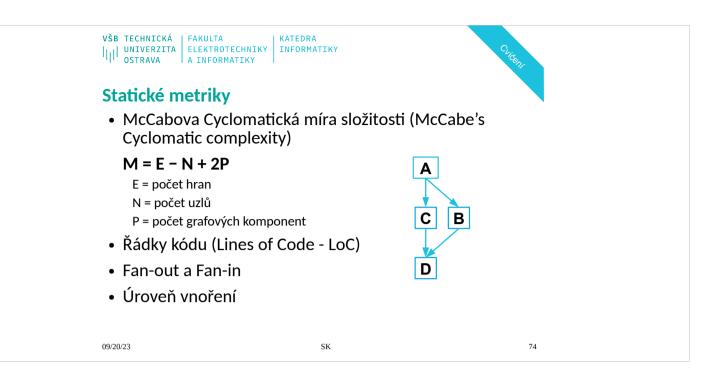

Print A; **Print B;**

END; END;

 Attempted use of a variable after it is killed

For example an attempt to read a variable outside its scope.

• Attempted use of a variable before it is

- <u>McCabe's Cyclomatic complexity</u> Is defined as the number of decisions in a program or control flow graph + 1. M = E N + 2P where
- M = cyclomatic complexity
- E = the number of edges of the graph
- N = the number of nodes of the graph
- P = the number of connected components.

Implications for Software Testing

M is a lower bound for the number of possible paths through the control flow graph. *M* is an upper bound for the number of test cases that are necessary to achieve a complete branch coverage.

• <u>Lines of Code (LoC)</u> Lines of code. It's a common measurement of the size of a program.

Fan-out and Fan-in

Fan-out is the amount of modules a given module calls. Modules with high Fan-out are often found in the upper part of the call tree.

Fan-in is the amount of modules that *call a specific module*. Modules with high Fan-in are often found in the lower part of the call tree.

If a module has both high fan-in and fan-out, consider to redesign it.

Nesting levels

For example many IF-statements nested into each other get a deep nesting level. This means that the code is difficult to understand. It is even worse when the cyclomatic complexity is also high.

One nesting level: IF X > 5 THEN PRINT "BIG"; ELSE PRINT "SMALL";

ENDIF;

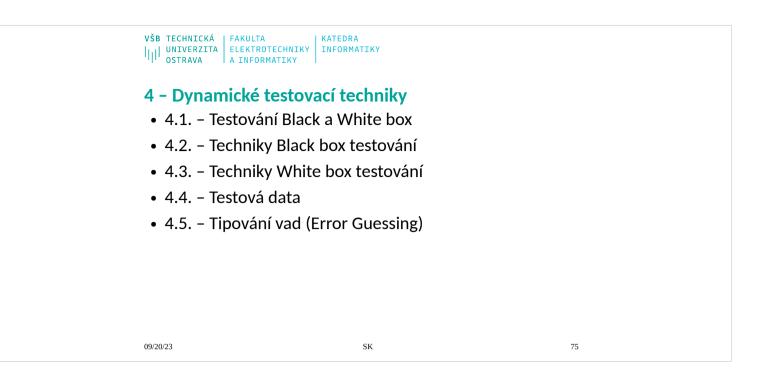

Who nesting levels:

IF X > 5 THEN IF X < 10 THEN PRINT "BIG UNIT";

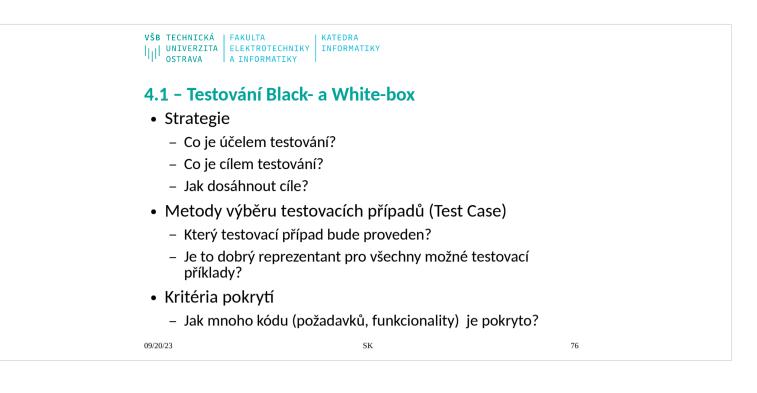

ENDIF; FI SF

_SE IF X != 0 THEN PRINT "SMALL UNIT";

ENDIF; ENDIF;

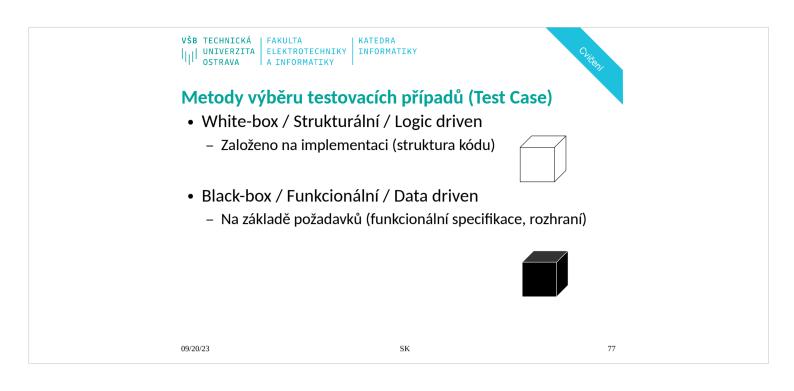

This part deals with dynamic testing techniques – methods that use executable test cases. These techniques are further divided into two groups (white-box and black-box testing techniques).

A good way of dealing with a testing problem is to first clarify the purpose of testing, then to define a goal and finally to develop a strategy for how to reach the goal.

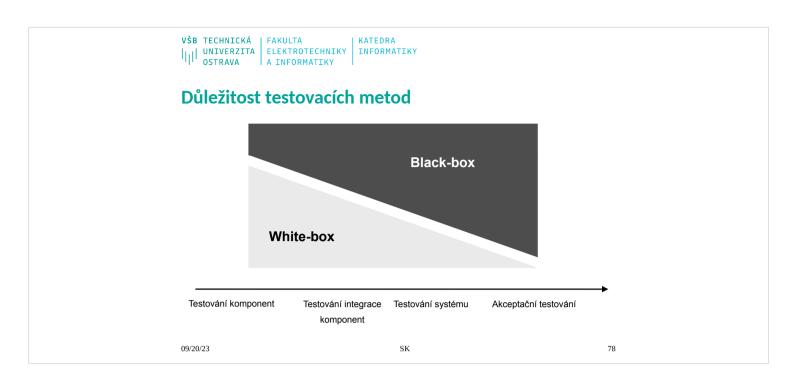

Once the goal has been defined, a test case selection strategy can be constructed. The obvious strategy would be to test everything, but due to infinite possibilities of choosing input this strategy is simply not feasible. Thus we need to carefully select the test cases that are to be executed. These test cases should be good representatives of all the possible test cases. To simplify the selection there exists a large number of test case selection methods, most of them are associated with coverage criteria to determine when to stop testing.

Test cases for dynamic execution are usually divided into two groups depending on the source of information used for creating the test case.

- <u>White-box</u>
- Test cases are based on information about the implementation of the test object (structure of the code). The inputs of white-box test cases are generated from the implementation information (from the code). The testing is based on the program logic.
- <u>Black-box</u>

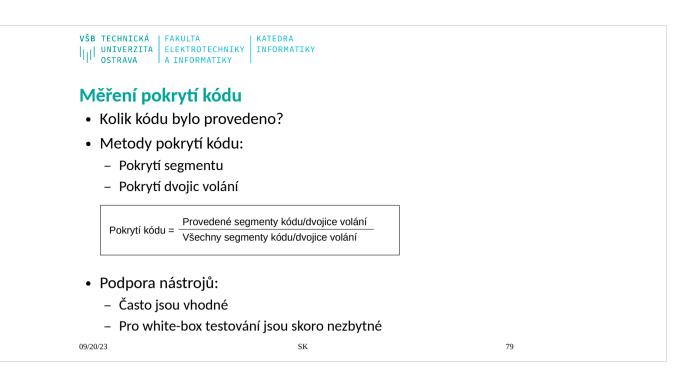

Test cases are aimed at testing the functionality of the test object. The inputs of black-box test cases are taken either from the requirements or from a model created from the requirements. Testing is based on inputs and

The two types of test cases are used a little bit differently in the development lifecycle. Whitebox test cases are mostly used in the early test phases of the development lifecycle and are of less usage higher up in the testing hierarchy.

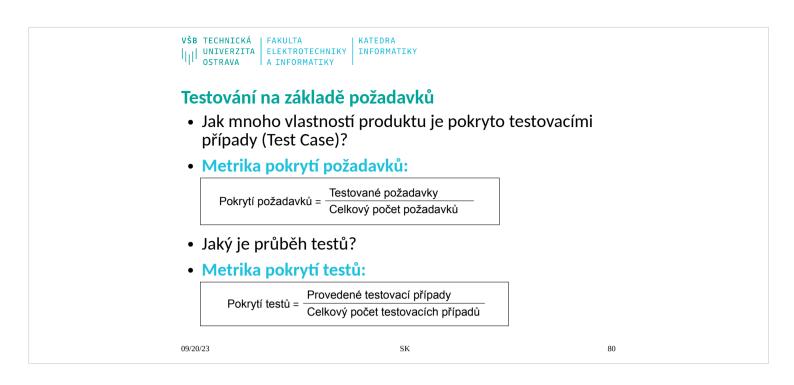

There are two reasons for this:

- 1. The most important is that most white-box methods require extensive knowledge of the code and other parts of the implementation. Later test phases are usually performed by dedicated test specialists with neither deep implementation knowledge nor access to this information.
- The other reason for not using white-box test case selection methods in later test stages is related to coverage. White-box test cases are usually more fine grained than black-box test cases. Fine grained test case selection methods require a large number of test cases in order to reach high coverage.
- Black-box testing techniques are used throughout the development lifecycle. The main advantage with black-box testing techniques is that they only depend on the requirements, which means that test cases can be prepared before the implementation is complete.
- Both methods are important. If only white-box testing would be performed, some requirements are not tested (performance requirements). On the other hand if only black-box test cases are used, some parts of the code might remain untested (special features called when a certain value is entered in a certain cell).

Code coverage metrics respond the question – How much of the code is being executed? There are usually 2 metrics:

- <u>Segment coverage</u>
- A segment is a set of program statements that are executed unconditionally or executed conditionally based on the value of some logical expression. 85% is a practical coverage value.
- <u>Call-pair coverage</u>
- A call pair is an interface whereby one module invokes another. Call-pair coverage is especially useful integration testing to ensure that all module interfaces are exercised. 100% is a practical coverage value.
- As already has been mentioned, white-box testing techniques use implementation information to derive the input part of the test cases. Most often some aspect of the code, for instance the source code statements, is used for this purpose. Even with quite small programs, the task of keeping track of which statements that have already been tested and which statements that yet remain to be tested is quite difficult. The solution to this problem is to use a tool. There are a large number of *commercial code coverage* tools available for this. They all work in the same manner: before the source code of the object to be tested is compiled, the code is instrumented by adding extra instructions at strategic places in the original code. This is done by the tool.
- The source code with the extra instructions is then compiled as usual and test cases are then executed in the normal way. The added instructions continuously log the progress of the testing and from the results of the logging instructions the tool can calculate which parts of the code that have been executed. Obviously the extra inserted instructions consume execution resources thus distorting performance measurements, so this type of tool is not appropriate during system testing.
- Nevertheless, the use of such tools increase both the quality and the productivity of the testing in the earlier test phases.

The basic for all black-box testing is the requirements.

The simplest but still structured way of creating test cases is to write one test case for each requirement. The main drawback with this approach is that most requirements require more than one test case to be tested thoroughly, and different requirements require a different amount of test cases. In this case we can create the <u>coverage matrix</u> that tracks requirements to test cases and vice versa. This feature is usually included in test management tools.

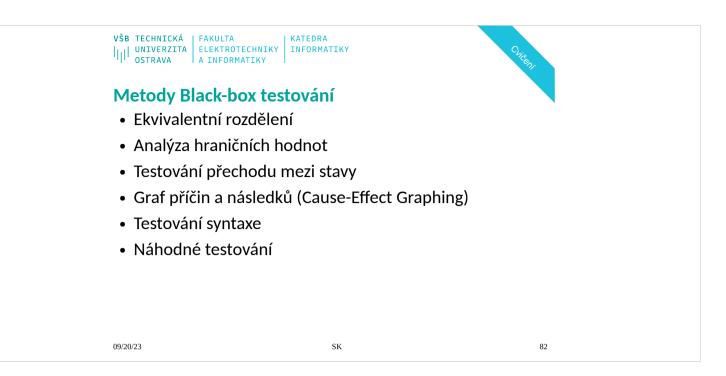

<u>Requirement Coverage</u> responds the question: How much of the product's features is covered by test cases?

Test Coverage responds the question: What's

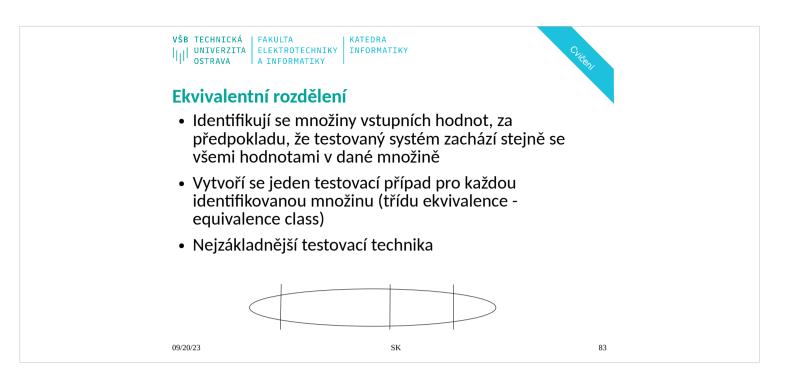

A more elaborate way of creating black-box test cases is to transform a set of requirements into a model of the system and derive the test cases from the model instead of directly from the requirements.

- In most model-based testing techniques there are well defined coverage criteria which are simple to calculate and interpret.
- The main drawbacks with models are limited scope and validation. Often the purpose of the model and the modeling technique used, limits the scope of the model. For instance a syntax graph only captures the syntax of a language. The semantic of that language must be covered somewhere else. The result is that several models need to be developed and used in order to get a reasonable

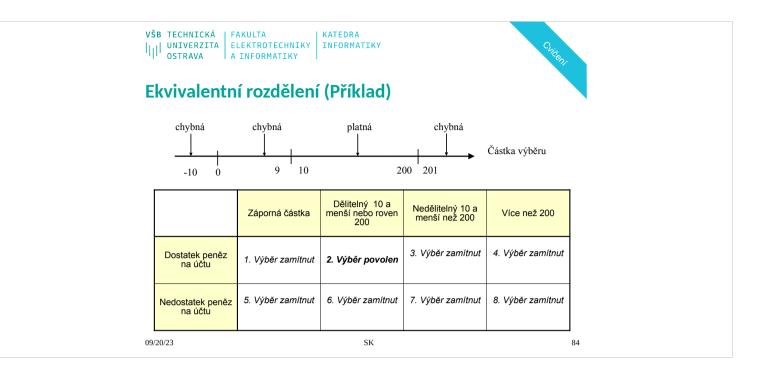

<u>Cause-Effect Graphing</u>

- A model based method, which relates effects with causes through Boolean expressions. The main focus is on different combinations of inputs from the equivalence classes. Cause-effect graphing is a way of doing this whilst avoiding the major combinatorial problems that can arise.
- <u>Syntax Testing</u>
- A model based method, which focuses on the syntax or rules (how different parts may be assembled) of a language (used during implementation). This method generates valid and invalid input data to a program. It is applicable to programs that have a hidden language that defines the data. Syntax generator is needed.

Equivalence class partitioning is one of the most basic black-box testing techniques. The underlying idea is that the input domain can be divided into a number of equivalence classes. The characteristic of an equivalence class is the assumption that all values belonging to that class are handled in exactly the same manner by the program.

- If this assumption is true, then it would suffice to select one single test case for each equivalence class, since multiple test cases from the same equivalence class would repeat the same test.
- Coverage is measured by dividing the number of executed test cases, i.e. the number of tested equivalence classes by the total number of equivalence classes.

- Example: "A withdrawal from an ATM (Automatic Teller Machine) is granted if the account contains at least the desired amount. Furthermore, the amount withdrawn must be an even number of 10 EUR. The largest amount that can be withdrawn is 200 EUR."
- By analyzing the requirements we find several different independent dimensions to this problem:
- Is there enough money in the account?
- Is the desired amount an even 10-number?
- Is the desired amount outside the correct 0-200 range?

One way to organize the information is to make a table as above. Each cell in the table represents an equivalence class, which means that there should be eight test cases to solve this testing problem with equivalence partitioning.

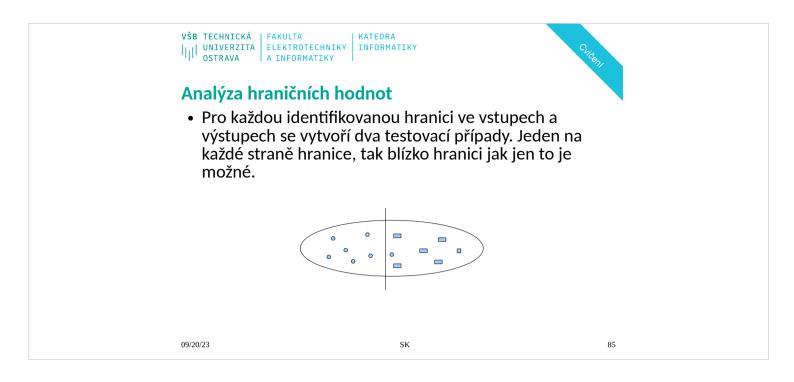

In this example one could argue that negative withdrawal is not technically possible, and even if it was possible, the amount of money in the account would be irrelevant.

This discussion illustrates two difficult questions: how much should we really test? And which tests are most important?

Mostly this boils down to a matter of taste. Our view is that it is better to include too much when designing test cases that to miss vital functionality. Test cases should however always be assigned a priority based on importance to the end user and importance to future testing. High priority test cases above could be 2, 3, 4 and 6.

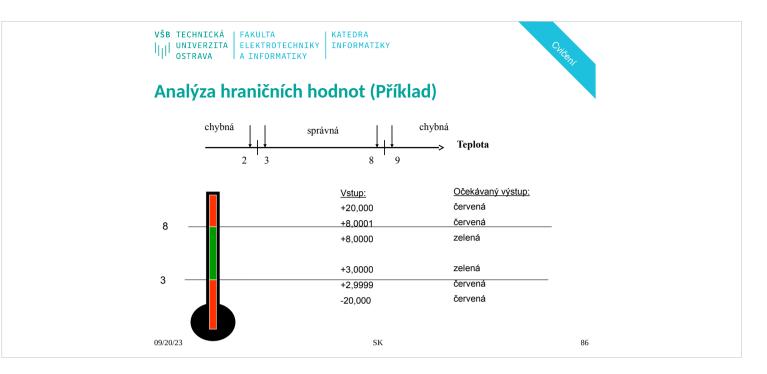

Medium priority test cases above could be 2, 3, 4 and 6 Medium priority test cases above could be 7 and 8.

Low priority test cases above could be 1 and 5.

Boundary Value Analysis is a refinement of equivalence class partitioning. Instead of choosing any representative from each equivalence class, interest is focused around the boundaries of each class. The idea is to select one test case for each boundary of the equivalence class. The properties of a test case is thus that is belongs to a defined equivalence class and that it tests a value that it is preferable on, or at least reasonably close to one of the boundaries of the equivalence class.

The main reason why boundaries are important is that they are generally used by programmers to control the execution of the program, for instance through if- or casestatements. Since the boundaries are being

The temperature range can be divided into three intervals (equivalence classes).

1. From --infinity (-273?) to but not including +3,0000 resulting in a red light

2. From +3,0000 to +8,0000 resulting in green light

3. From but not including +8,0000 to + infinity

When using boundary value analysis, there should be one test case for each boundary in every equivalence class:

Test case 1a:

Negative infinity, even -273 is a little hard to create, and furthermore not very likely to occur. So a good (?) estimation could be -20,000.

Test case 1b:

Here we have the problem of being close enough to the boundary since being on the boundary is outside this interval. Is five valid digits a good estimate?

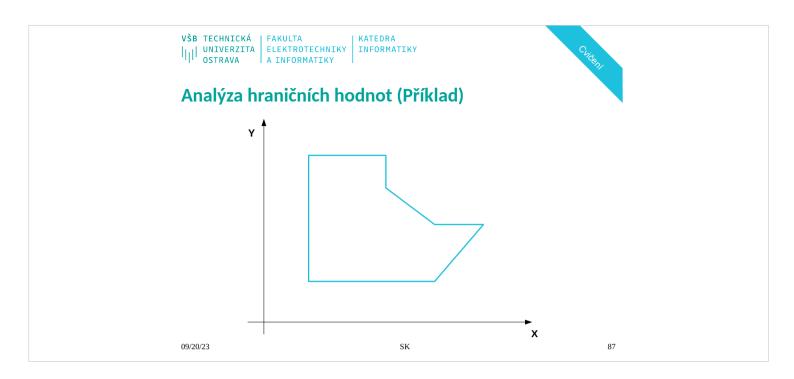

Test cases 2a and 2b:

Both boundaries are inside the interval so these values are the ones to choose.

Test case 3a:

Same discussion as in 1b.

Test case 3b:

The temperature range can be divided into three intervals (equivalence classes).

- 1. From –infinity (-273?) to but not including +3,0000 resulting in a red light
- 2. From +3,0000 to +8,0000 resulting in green light

3. From but not including +8,0000 to + infinity

When using boundary value analysis, there should be one test case for each boundary in every equivalence class:

Test case 1a:

	íních hodnot -		b
Delekce vady	y v případě nejč	castejsich chy	D:
Požadavek	Vada v imp.	ER (EP)	AHH (BVA)
A < 18	A < =18	Ne	Ano
A < 18	A > 18	Ano	Ano
A < 18	A < 20	Možná	Ano

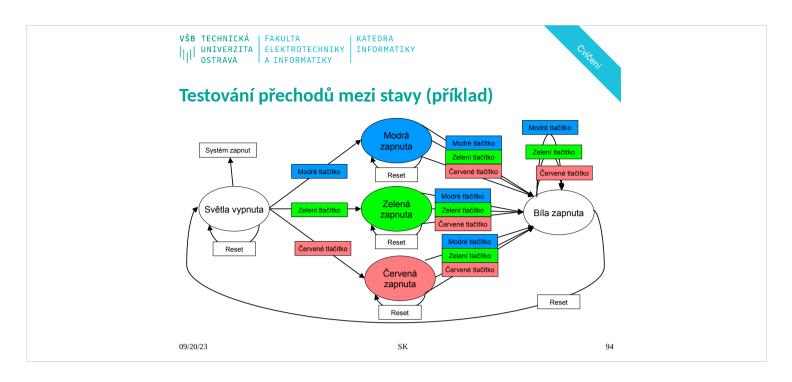

Which is better, Equivalence Partitioning (EP) or Boundary Value Analysis (BVA)?

- The answer depends on what we mean by better. Test cases made by BVA will catch more types of errors, but on the other hand there will be more test caes, which is more time consuming.
- If you do boundaries only, you have covered all the partitions as well:
- Technically correct and may be OK if everything works correctly
- If the test fails, is the whole partition wrong, or is a boundary in the wrong place – have to test mid-partition anyway
- Testing only extremes may not give confidence for typical use scenarios (especially for users)

- State machine based testing is a quite useful model based black-box testing technique, since any type of functionality that can be represented as a finite state machine can be tested using this technique.
- The first step when using state machine testing is to construct the model itself. Sometimes, state machines are used by designers and constructors as implementation tools. In those cases, the state machines can of course be used directly. Otherwise the state machine model has to be constructed based on the requirements by the testers.
- Often during construction of the state machine models, faults are found. One of the key properties with a state machine is that all input types can occur regardless of the state of the machine. If a state machine model previously has not been drawn, there are almost always disregarded combinations of state and input, which are very easily discovered when building the model.
- When the model is finished, the next step is to construct test cases from it. There are several different strategies. The simplest and least powerful is to cover each state in the model at least once. As soon as there are more than one way of reaching a particular state, state coverage will most likely leave some transitions untested. A more elaborate strategy is therefore to focus on the transitions between the states. O-switch coverage requires one test case for each possible transition in the model. 1-switch coverage requires a test case for every possible pair of consecutive transitions and finally n-switch coverage requires a test case for every possible n+1 consecutive transitions in the model.

Example:

- Four keys, four lamps
- After the start, all lamps are off
- A colored key turns "its" lamp on, if all lamps are off Next colored key turns the white lamp on and the colored off
- The Reset key turns the white lamp off and resets the system

There are 5 states. To determine how many transitions there are, it is helpful to calculate the number of transitions out from each state (in our case there are 4 transitions):

(5*4+1) = 21 transitions (0-switch) (5*4*4+4) = 84 pairs of transitions (1-switch)

It's easy to understand that 'time-outs', common is real-time applications, will make it even more advanced.

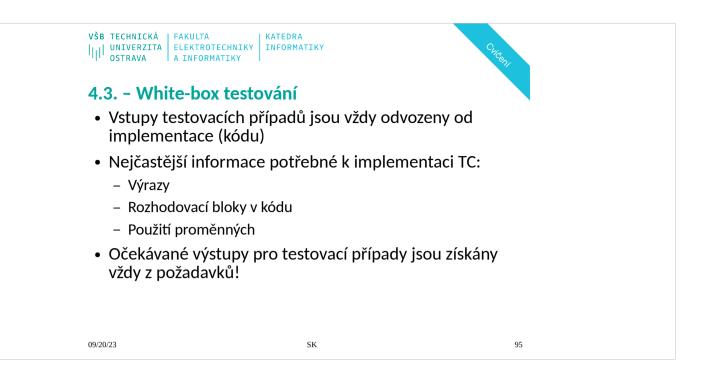

Create test cases:

- A) touching each state
 - 5 test cases sufficient for such a simple system
- B) using each transition (0-switch coverage)
 21 test cases if the white lamp did not turn on after the green lamp, it is necessary to use "each transition" to catch this fault
 C) using every possible pair of transitions (1-switch coverage)

 - 84 test cases if the *Reset* key does not work after the red lamp and the blue key (but works after all other keys), finding this fault requires trying "all pairs of transitions"

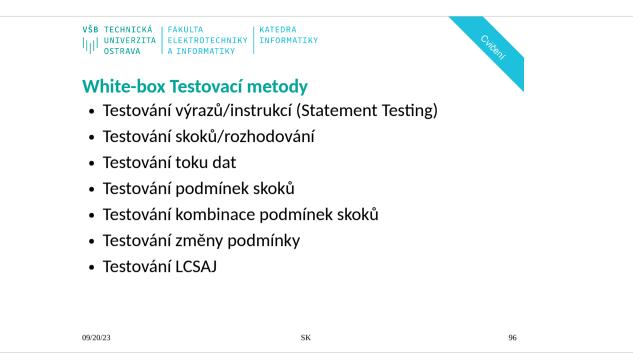

To discover a fault which, for example, causes the system to hang after a thousand loops, still another strategy is required.

The number of tested inputs is another dilemma. Should all possible inputs be tried in each state? The strategy described here do not answer this question.

When creating white-box test cases the basis in the implementation. The input part of the test case is derived from the implementation.
Commonly used implementation properties include code structure and how variables are used in the code. Less common but nevertheless interesting implementation properties are call-structures and process/object interactions.
Regardless of the white-box test method

chosen, expected output is always extracted from the requirements and not from the implementation itself.

<u>Statement Testing</u>

The idea with statement coverage is to create enough test cases so that every statement in the source code has been executed at least once

- Branch/Decision Testing
- The idea with decision coverage is to execute every single decision in the code at least twice (both possible outcomes of the decision should be executed in order to reach full decision coverage)
- Data Flow Testing

Test cases are designed based on variable usage within the code

Branch Condition Testing

A test case design technique in which test cases are designed to execute branch condition outcomes

Test cases shall be designed to exercise individual Boolean operand values within

decision conditions.

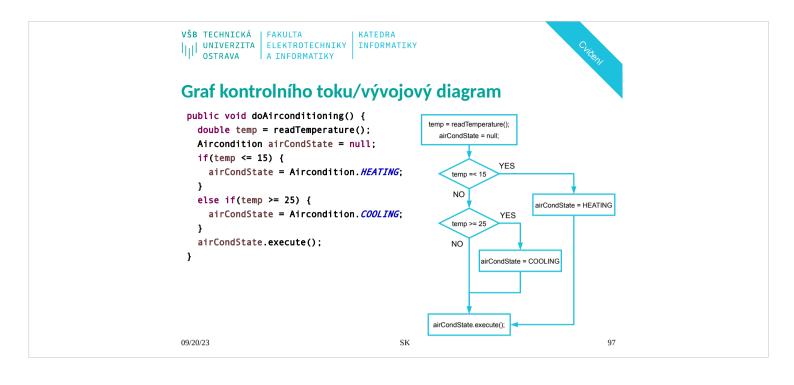

- Branch Condition Combination Testing
- A test case design technique in which test cases are designed to execute combination of branch condition outcomes
- Test cases shall be designed to exercise combinations of Boolean operand values

within decision conditions.

<u>Modified Condition Decision Testing</u>

A test case design technique in which test cases are designed to execute branch condition outcomes that independently affect a decision outcome

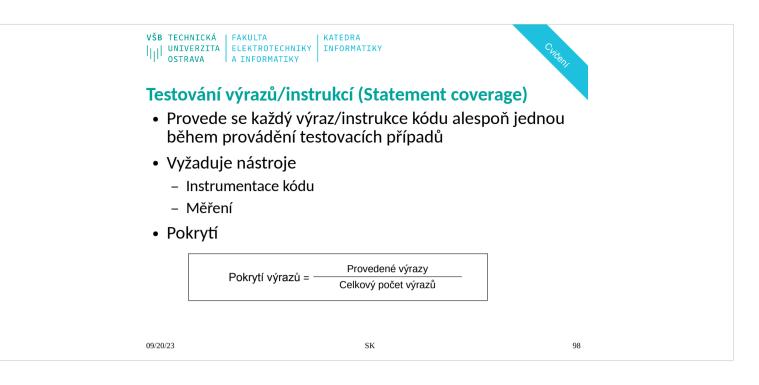

- Test cases shall be designed to demonstrate that Boolean operands within a decision condition can independently affect the outcome of the decision.
- LCSAJ Testing
- Linear Code Sequence And Jump (LCSAJ) Select test cases based on jump-free sequence of code. It consists of the following three items: the start of the linear sequence of executable statements, the end of the linear sequence, and the target line to which control flow is transferred at the end of the linear sequence.

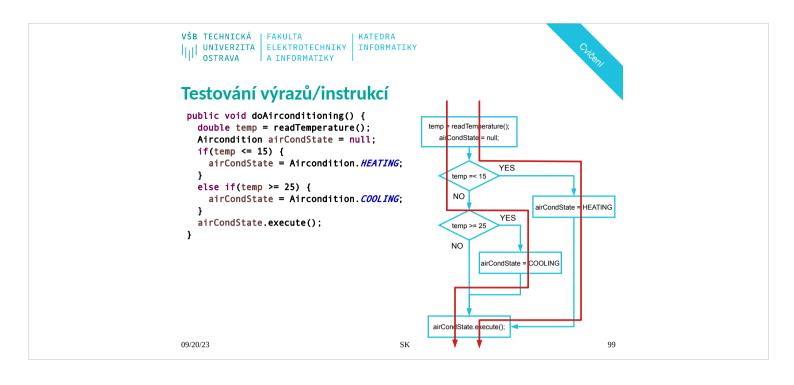

This is a small piece of code, which implements the temperature regulation. The function "adjust_temperature" is called without arguments. The first thing it does is to read the current temperature, and then depending on the value, either the heater is switched on, the cooler is switched on, or the system is left untouched. The global variable *control* holds the current setting of the heater and cooler.

To the right the is the corresponding control flow graph. To aid the understanding of the control flow graph strategic parts of the code may be inserted in the diamonds and boxes.

<u>McCabe's cyclomatic complexity measure</u>: No. of diamonds + 1 (2 + 1 = 3) – it says that the more decisions there are in a piece of code,

- Statement coverage is a fundamental whitebox testing technique. This idea of statement coverage is to create enough test cases so that every statement in the source code has been executed at least once.
- The workflow when using statement coverage is to first execute all existing black-box test cases that has been created while monitoring the execution. This monitoring is in all but the simplest test cases performed with tool support. When all black-box test cases have been executed, the tool can report which parts of the code that remain untested. The idea is now to construct new test cases that will cover as many of the remaining statements as possible. Start with the part of the code that should be reached, walk

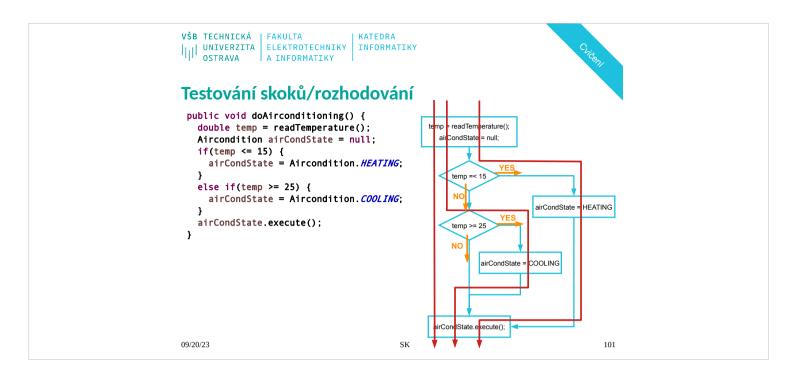

When creating test cases for statement coverage we can make use of the control flow graph. We know the statement coverage requires statements in the code to be executed. We also know that the boxes and the diamonds represent all the statements in the code.

- By following the two blue arrows through the code we cover all the diamonds and all the boxes are covered and thus we have statement coverage (according to the relation with McCabe measure there should be three or less test cases and in this case two were enough).
- By examine the relation we can now also deduce that in the optimal choice of test cases, number of test cases for decision

Branch coverage and decision coverage are two names for the same thing.

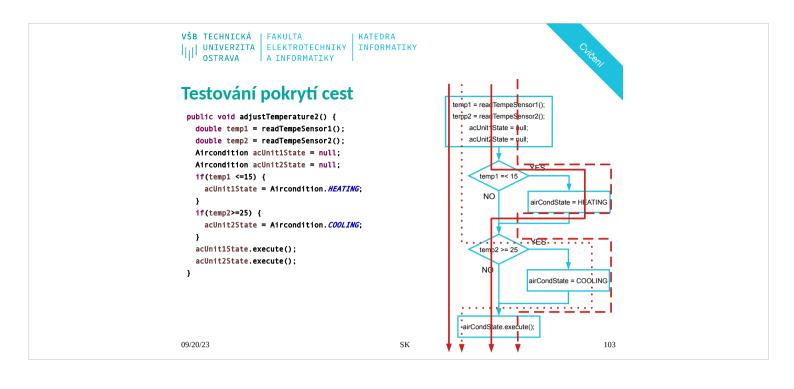

- Decision coverage is a technique similar to statement coverage. The idea with decision coverage is to execute every single decision in the code at least twice. Both possible outcomes of the decision, i.e. true and false, should be executed in order to reach full decision coverage.
- By the first glance statement and decision coverage seem to yield exactly the same test cases, since executing every decision with both true and false outcomes will result in all statements being executed, and in order to execute all statements all outcomes of every decision needs to be executed. However this is not entirely true. There is one case in

Modified Condition Decision Testing and Coverage

- Modified Condition Decision Coverage (MCDC) is a pragmatic compromise which requires fewer
- test cases than Branch Condition Combination Coverage. It is widely used in the development of

avionics software, as required by RTCA/DO-178B.

Modified Condition Decision Coverage requires test cases to show that each Boolean operand (A, B

and C) can independently affect the outcome of the decision. This is less than all the combinations (as

required by Branch Condition Combination Coverage).

- For the example decision condition [A or (B and C)], we first require a pair of test cases where
- changing the state of A will change the outcome, but B and C remain constant, i.e. that A can
- independently affect the outcome of the condition:

- Professional data generators
 - Data generator controlled by syntax and semantics
 - Stochastic data generator
 - Data generator based on heuristic algorithms
 - Combination of previous methods
- Modified production data

The data must be degraded (omitting sensitive data) before using as test data. The advantage is that we have test data that are close to real production data. The disadvantage is that data must be modified to have all combinations needed for test cases.

Data administration tools

E.g. File-AID/Data Solution (Compuware), RC Extract (CA), Startool/Comparex (Serena), Relational Tools for Servers (Princeton Softech), detailed knowledge of DB structure and links is needed. Tools are ready for it's sometimes difficult and laborious.

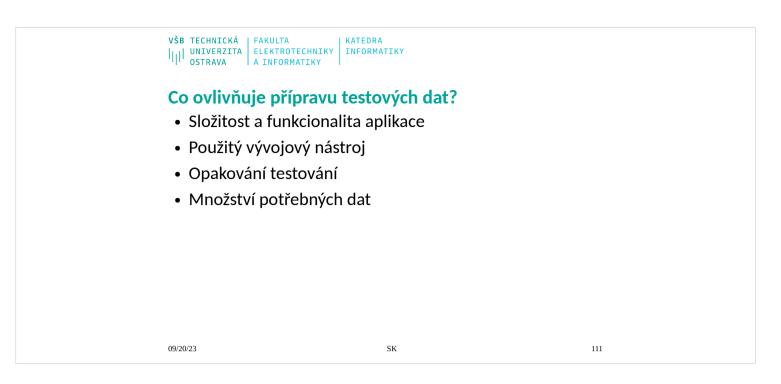

• Own data generators

Development resources are needed, suitable when combining with Excel. Sophisticated data can be generated which are tailored to the needs of test cases.

• <u>Excel</u>

DB tables are stored in Excel, SQL scripts generate DB structures tailored to the needs of test cases. The initial data has to be stored manually – laborious.

- <u>Test automation tools</u>
- E.g. WinRunner, QuickTest Pro, LoadRunner, SilkPerformer, etc. Data can be generated during nights, test data can be stored to database, Excel or text files. Tools are often expensive.

- <u>Complexity and functionality of the</u> <u>application</u>
- It directly influences the range of testing, mutual linking and the amount of test data (financial systems must be tested in more details than registration systems).
- <u>Used development tool</u>
- In case of using test automation tools, the development environment must be compatible with used test tools.
- <u>Repetition of testing</u>
- The efficiency of using test automation tools is higher the higher repetition of the same test cases (regression testing) is (valid not only for test data preparation but also for test execution.
- <u>The amount of data needed</u>

<u>Don't remove old test data</u>

Create test data archive for future use.

<u>Describe test data</u>

Create your own information system from metadata describing content, form and effectiveness of test data.

• <u>Check test data</u>

Test data must be error free.

• <u>Expected results</u>

Don't underestimate time needed for setting expected results for generated test data.
